COLLEGE OF AGRICULTURE, EXTENSION SERVICE IN AGRICULTURE AND HOME ECONOMICS
URBANA, ILLINOIS

Annual Farm Business Report

ON EIGHTY SEVEN FARMS IN FARMING-TYPE AREA 1, 1939

By P. E. Johnston, J. B. Cunningham, and E. M. Hughes

Farm earnings of accounting farms in Farming-Type Area 1 were higher in 1939 than in 1938 or 1937. The net earnings per acre averaged \$10.64 in 1939, \$9.55 in 1938, \$8.69 in 1937, and \$14.35 in 1936. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 1
Dairy and Truck

Since the value of farm products used in the household was not included in the records prior to 1938, the carnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.43 in 1938 and \$1.41 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

High crop yields and more livestock, accompanied by increased industrial activity and improved demand for farm products, especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

LY R. J. Mutti supervised the closing of the farm accounts and the preparation of the tables used in this report. The farm accounts project was conducted in cooperation with the farm bureaus in the following counties and was supervised by the farm advisers indicated:

J. H. Brock, McHenry County

H. S. Wright, DuPage County

A. C. Johnson, Kane County

D. M. Chalcraft, Boone County

H. C. Gilkerson, Lake County

C. A. Hughes, Cook County

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes. -- The year 1939 was the fourth consecutive year of increasing inventories, the increases averaging \$887 in 1939, \$586 in 1938, \$171 in 1937, and \$1,237 in 1936 (Table 1). The largest increases in 1939 were in livestock and feed and grain. The increased value of feed and grain represented higher prices at the end of the year as well as larger quantities of grain on hand (Page 1 and Fig. 2). The average amounts of grain on hand in Area 1 at the two inventory periods follow:

	Beginning of year (bushels)	End of year (bushels)
Corn	1,540	1,795
Oats	710	581

Cash receipts.--Cash receipts were the smallest in the last four years, averaging \$5,064 in 1939 (Table 1). Livestock receipts, principally dairy sales and hogs were smaller this year than last. AAA payments and grain sales were larger in 1939 than in 1938. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs.

Cash expenses. -- Cash expenses were smaller in 1939 than in either 1938 or 1937. Less money was spent for machinery and equipment, but more was spent for cattle and feeds, in 1939 than in 1938.

Earnings. -- Cash receipts exceeded cash expenses in 1939 by \$1,430, or by a smaller margin than that for any other year during the past four years. Cash balance, the difference between these receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments, and savings.

The amounts deducted for operator's and family labor remained rather uniform during the 4-year period, a difference of only \$56 occurring between the low year, 1939, and the high year, 1937. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$50 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$1,818 in 1939 compared with \$1,776 for 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm earnings. -- A wide variation was found in earnings on the farms in Area 1; for example, 30 farms earned less than 5 percent on the investment, with an average rate earned of 1.9 percent, but in contrast 24 farms earned 9 percent or more, with an average rate earned of 12.0 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had a loss of \$246 for labor and management earnings as contrasted with a gain of \$2,402 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the area was as follows:

				Capital			
Rate	Number	Average	Acres	in-	Gross	Net	Labor and
earned on	of	rate	per	vested	earnings	earnings	management
investment	farms	earned	farm	per farm	per farm	per farm	earnings

5 to 9	33	7.1	178	29,307	4,960	2,087	1,146
9 or more	24	12.0	181	26,444	6,012	3,179	2,402

Comparison of Farms According to Quality of Land

The 87 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms 36 had 85 percent or more of land area tillable, and 51 had less than 85 percent tillable. The average percent tillable was 91.7 for the former group and 69.8 for the latter group.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar quality of land as well as with the average of all accounting farms (Tables 2 and 3).

The capital investment averaged \$25,747, or \$162 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$26,899, or \$150 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases were the same for the two groups of farms. The expenses and net decreases, however, were \$208 smaller on the farms of higher-quality land than on those of lower-quality land. The rate earned on investment was 7.5 percent and 6.0 percent, and the labor and management earnings were \$1,144 and \$920, respectively, for the two groups of farms.

The farms on higher-quality land were 21 acres smaller than those on lower-quality land; yet the former had 15 acres more land in crops. They also had a larger percent of tillable land in soybeans and a smaller percent in oats. The amount of livestock per farm was practically the same for the two groups of farms, as indicated by the value of feed fed to productive livestock and the capital invested in productive livestock (Tables 3 and 2).

CHART FOR STUDYING THE EFFICIENCY OF VARIOUS PARTS OF YOUR BUSINESS, FARMS WITH MORE THAN 85 PERCENT OF THE LAND AREA TILIABLE

Accounting Farms in Farming-Type Area 1, 1939

The numbers above the lines across the middle of the page are the averages for the 36 farms included in this group for the factors named at the top of the page. By drawing a line across each column at the number measuring the efficiency of your farm in that factor, you can compare your efficiency with that of other farmers in your locality.

Expense Factors Labor cost2/ Per crop acre \$ Per \$100 gross earnings	11.12	\$ 8.70 29	\$ 8.72 25
Horse and machinery cost per crop acre \(\frac{1}{2} \)	6.54	5.36 1.23 1.33	1.56

Larger crop yields per acre on the farms on higher-quality land, which amounted to 2.4 bushels of corn, 2.4 bushels of oats, 1.9 bushels of barley, indicate the relative productive level of the land on two groups of farms.

The operating expenses per acre averaged \$15.92 on the farms with the most tillable land and \$15.14 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$2.42 smaller on the farms with the larger percent of tillable land.

The livestock-efficiency factors, such as poultry returns per hen, hog returns per litter of pigs farrowed, and dairy returns per cow milked, were not appreciably affected by the quality of land. These factors indicate that the two groups of farms were operated with about the same degree of efficiency. Therefore, it may be assumed that the differences in organization, land use, crop yields, and costs were principally due to the differences in the productivity of the land on the two groups of farms.

Source of Income

The 87 farms were divided into 3 groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column in Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years.

The returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, according to 5-year averages of complete cost studies (1933-1937), follow: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the 3 groups of accounting farms with different classes and proportions of livestock varied widely in the returns per \$100 worth of feed fed.

Differences in expenses are significant for the 3 groups of farms. Labor input was highest on the dairy farms, where 24.9 months of labor were used. The labor cost per crop acre averaged \$11.12 on the dairy farms. This was about \$2.50 per crop acre higher than for the general farms. Likewise, both the horse and machinery and the improvement costs were higher on the dairy farms than on the general farms. In spite of the higher expenses the dairy farms showed the best earnings. The rate earned was 7.1% for the dairy farms and 6.4% and 6.5% for the general farms.

Size of Farm As Related to Earnings

The farm records in Farming-Type Area 1, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 26 largest farms had labor and management earnings which averaged \$1,430 as contrasted with \$618 for the 27 smallest farms. The earnings, as measured by the rate earned on the investment, were 7.5% for the former group and 5.7% for the latter group. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent) the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate carned averages less than the capitalization rate.

The smaller farms were operated more intensively than were the larger farms. This variation was indicated by the much higher gross earnings per acre, by the larger proportion of total land tillable, by the higher land values, and by the larger amount of feed fed per acre to productive livestock.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. A tabulation of farm account records by counties and groups of counties indicates some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income (Tables 6 and 7).

In this report an average was calculated for each county from which 30 or more records were received. Averages were made in some instances with less than 30 records if it was necessary to eliminate some records because they were incomplete or not typical for the area. In any tabulation containing as few as 30 records, part of the variation from county to county is due to the fact that the averages do not represent a cross section of the county.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year even though these records are from farms with efficiency which is higher than average.

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms unier seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1, 1959.

Livestock numbers on Illinois farms increased sharply in 1939 even though 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939; dairy cows, 2 percent; beef cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were greater at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Frices of important farm products. -- Frices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and roultry were lower. Most of these price increases occurred during the last four months of the year.

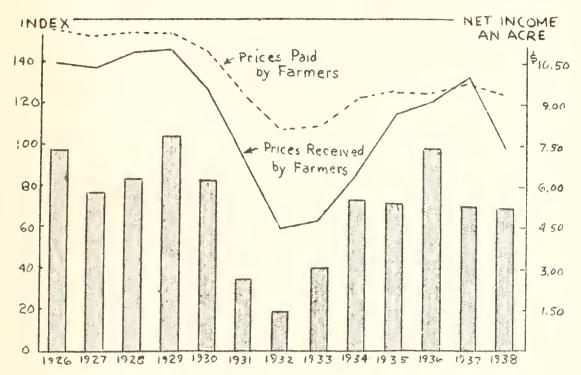

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

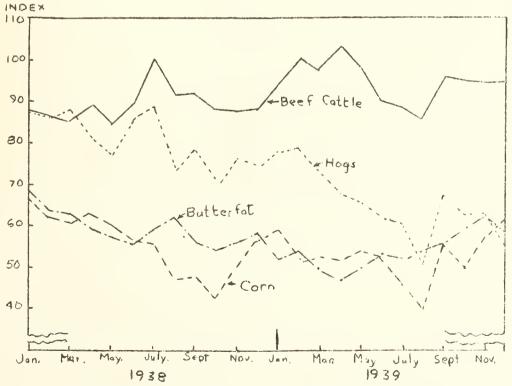

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 3 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and oats, 97.

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low oat yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corm, cats, wheat, and soyleans. (Data from Illinois Cooperative Crop Reporting Service.)

FARM BUSINESS REPORT . . . 1939

FARMING-TYPE AREA TWO Northwestern Mixed Livestock Area

DEPARTMENT OF AGRICULTURAL ECONOMICS, UNIVERSITY OF ILLINOIS

COLLEGE OF AGRICULTURE, EXTENSION SERVICE IN AGRICULTURE AND HOME ECONOMICS

URBANA, ILLINOIS

Annual Farm Business Report

ON FOUR HUNDRED FIFTY-FOUR FARMS IN FARMING-TYPE AREA 2, 1939

By P. E. Johnston, J. B. Cunningham, and E. M. Hughes 1

Farm earnings of accounting farms in Farming-Type Area 2 were higher in 1939 than in 1938. The net earnings per acre averaged \$12.65 in 1939, \$9.62 in 1938, \$8.46 in 1937, and \$16.43 in 1936. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 2
Mixed Livestock

Since the value of farm products used in the household was not included in the records prior to 1938, the earnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.28 in 1938 and \$1.20 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

High crop yields and more livestock, accompanied by increased industrial activity and improved demand for farm products, especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

^{1/} R. J. Mutti supervised the closing of the farm accounts and the preparation of the tables used in this report. The farm accounts project was conducted in cooperation with the farm bureaus in the following counties and was supervised by the farm advisers indicated:

R. P. Johnson, DeKalb County

V. J. Banter, Stephenson County

C. E. Yale, Lee County

D. E. Warren, Ogle County

R. C. Smith, Rock Island County

H. E. Kearnaghan, Jo Daviess County

H. R. Brunnemeyer, Winnebago County

F. H. Shuman, Whiteside County

M. P. Roske, Carroll County

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes.--The year 1939 was the fourth consecutive year increasing inventories, the increases averaging \$1,191 in 1939, \$448 in 1938, \$228 in 1937, and \$1,382 in 1936 (Table 1). The largest increases in 1939 were in feed and grain and in livestock. The increased value of feed and grain represented higher prices at the end of the year as well as larger quantities of grain on hand (Page 1 and Fig. 2). The average amounts of grain on hand in Area 2 at the two inventory periods follow:

Beginning of year (bushels)		End of year (bushels)
Corn	2,958	3,407
Oats	1,034	828
Wheat	21	27
Soybeans	47	55

Cash receipts.--Cash receipts reached the highest level in four years, averaging \$6,923 in 1939 (Table 1). Cattle and grain sales and AAA payments were larger in 1939 than in 1938, but hog and dairy sales were smaller. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs.

Cash expenses. -- Cash expenses were greater in 1939 than in any of the last four years. For every major item of expense, a greater amount was paid out in 1939 than in 1938.

Earnings. -- Cash receipts exceeded cash expenses in 1939 by \$1,936, or by a smaller margin than that for any other year during the past four. Cash balance, the difference between these receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments and savings.

The amounts deducted for operator's and family labor remained rather uniform during the 4-year period, a difference of only \$82 occurring between the low year, 1938, and the high year, 1936. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$50 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$2,645 in 1939 as contrasted with \$1,985 in 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm earnings...A wide variation was found in earnings on the farms in Area 2; for example, 30 farms earned less than 3 percent on the investment, with an average rate earned of 1.1 percent, but in contrast 43 farms earned 12 percent or more, with an average rate earned of 13.6 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had a loss of \$469 for labor and management earnings as contrasted with a gain of \$2,978 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the areas was as follows:

				Capital			
Rate	Number	Average	Acres	in-	Gross	Net	Iabor and
earned on	of	rate	per	vested	earnings	earnings	managemer

12 or more	43	13.6	204	28,248	6,280	3,846	2,978

Comparison of Farms According to Quality of Land

The 454 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms, 279 had 85 percent or more of land area tillable, and 175 had less than 85 percent tillable. The average percent tillable was 92.7 for the former group and 69.3 for the latter group.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar quality of land as well as with the average of all accounting farms (Tables 2 and 3).

The capital investment averaged \$36,862, or \$177 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$27,332, or \$129 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases were \$1,324 larger and expenses and net decreases \$417 larger on farms of higher-quality land than on those of lower-quality land. Dairy sales were \$227 smaller for the farms with the larger percent of land area tillable; whereas, the grain receipts were \$531 larger and cattle receipts \$678 larger. The rate earned on investment was 8.2 percent and 7.5 percent, and the labor and management earnings were \$1,717 and \$1,256, respectively, for the two groups of farms.

The farms on higher-quality land averaged 3 acres smaller than did the on lower-quality land; yet the former had 34 acres more land in crops. They also had a larger percent of tillable land in corn and soybeans but a smaller percent in oats, wheat, and hay and pasture. The amount of livestock per farm was large on the farms with the most tillable land, as is indicated by the value of feed fed to productive livestock and the capital invested in productive livestock (Tables 2 and 3).

CHART FOR STUDYING THE EFFICIENCY OF VARIOUS PARTS OF YOUR BUSINESS, FARMS WITH LESS THAN 85 PERCENT OF THE LAND AREA TILLABLE

Accounting Farms in Farming-Type Area 2, 1939

The numbers above the lines across the middle of the page are the averages for the 175 farms included in this group for the factors named at the top of the page. By drawing a line across each column at the number measuring the efficiency of your farm in that factor, you can compare your efficiency with that of other farmers in your locality.

Larger crop yields per acre on the farms on higher-quality land, which amounted to 3.4 bushels of corn, 3.5 bushels of oats, 1.2 bushels of barley, and 1.4 bushels of soybeans, indicate the relative productive level of the two groups of farms.

The operating expenses per acre averaged \$12.96 on the farms with the most tillable land and \$10.97 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$1.82 smaller on the farms with the larger percent of tillable land, but the combined cost per acre for improvements and taxes was \$.53 larger.

The livestock-efficiency factors, such as poultry returns per hen, hog returns per litter of pigs farrowed, and dairy returns per cow milked, were not appreciably affected by the quality of land. These factors indicate that the two groups of farms were operated with about the same degree of efficiency. Therefore, it may be assumed that the differences in organization, land use, crop yields, and costs were principally due to the differences in the productivity of the land on the two groups of farms.

Source of Income

The 454 farms were divided into six groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column in Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that generally the grain farms were located on the better land: high value of land per acre, large percent of land area tillable, and large percent of land in grain.

The returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, according to 5-year averages of complete cost studies (1933-1937) are as follows: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the six groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. The amount of feed fed per acre to productive livestock averaged \$17.86 on the cattle farms but only \$6.25 on the grain farms.

Differences in expenses are significant for the six groups of farms. Labor input was highest on the cattle farms, where 25.9 months of labor were used, and lowest on the hog farms, where 18.8 months of labor were used; horse and machinery cost per crop acre averaged \$5.69 on the dairy farms, \$5.59 on the cattle farms, \$5.55 on the hog farms, and only \$4.39 on the grain farms; improvement costs per acre ranged from \$1.64 on the dairy farms to \$1.15 on the grain farms; and land taxes ranged from \$1.21 on the grain farms to \$1.07 on the hog farms.

Size of Farm as Related to Earnings

The farm records in Farming-Type Area 2, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 13 largest farms had labor and management earnings which averaged \$3,690 as contrasted with \$967 for the 75 smallest farms. The earnings, as measured by the rate earned on the investment, however, did not vary greatly among the different size groups. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent), the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate earned averages less than the capitalization rate.

The smaller farms were operated more intensively than were the larger farms. This variation was indicated by higher gross earnings per acre and by larger amounts of feed fed per acre to productive livestock.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. A tabulation of farm account records by counties and groups of counties indicates some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income (Tables 6 and 7).

In this report an average was calculated for each county from which 30 or more records were received. Averages were made in some instances with less than 30 records if it was necessary to eliminate some records because they were incomplete or not typical for the area. In any tabulation containing as few as 30 records, part of the variation from county to county is due to the fact that the averages do not represent a cross section of the county.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year even though these records are from farms with efficiency which is higher than average.

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms unier seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1, 1939.

Livestock numbers on Illinois farms increased sharply in 1939 oven though 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939; dairy cows, 2 percent; beef cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were greater at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

<u>Frices of important farm products.</u>--Frices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these price increases occurred during the last four menths of the year.

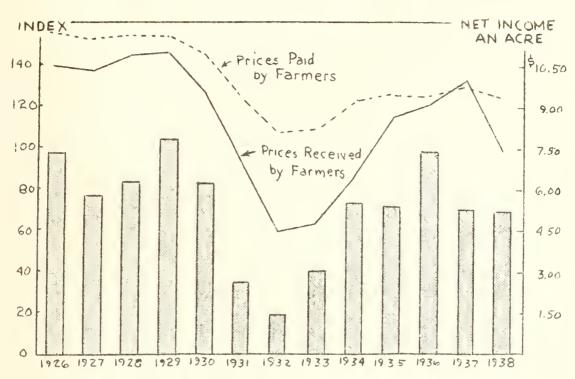

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

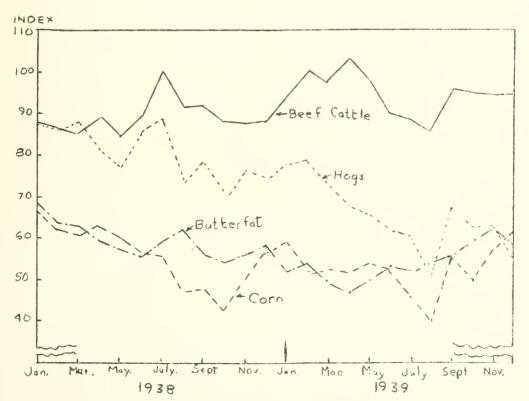

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 3 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and oats, 97.

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low oat yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corn, cats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

FARM BUSINESS REPORT . . . 1939

FARMING-TYPE AREA THREE Western Livestock and Grain Area

DEPARTMENT OF AGRICULTURAL ECONOMICS. UNIVERSITY OF ILLINOIS
COLLEGE OF AGRICULTURE, EXTENSION SERVICE IN AGRICULTURE AND HOME ECONOMICS
URBANA, ILLINOIS

Annual Farm Business Report

ON FIVE HUNDRED ELEVEN FARMS IN FARMING-TYPE AREA 3, 1939

By P. E. Johnston, J. B. Cunningham, and E. N. Searls 1

Farm earnings of accounting farms in Farming-Type Area 3 were higher in 1939 than in 1938. The net earnings per acre averaged \$14.06 in 1939, \$10.36 in 1938, \$10.83 in 1937, and \$13.14 in 1936. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 3
Mixed Livestock

Since the value of farm products used in the household was not included in the records prior to 1938, the earnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.13 in 1938 and \$1.04 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

High crop yields and slightly more livestock, accompanied by increased industrial activity and improved demand for farm products, especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

LY R. J. Mutti supervised the closing of the farm accounts and the preparation of the tables used in this report. The farm accounts project was conducted in cooperation with the farm bureaus in the following counties and was supervised by the farm advisers indicated:

H. K. Danforth, Henry County Paul V. Dean, Bureau County

R. G. Benbow, McDenough County

A. R. Kemp, Knox County

J. W. Whisenand, Peoria County

J. E. Watt, Fulton County

E. D. Peterson, Mercer County

A. J. Rehling, Henderson County

L. L. Norton, Hancock County

E. H. Walworth, Warren County

L. J. Hager, Marshall-Putnam County Wayne A. Gilbert, Stark County

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes.--The year 1939 was the fourth consecutive year of increasing inventories, the increases averaging \$1,540 in 1939, \$581 in 1938, \$1,067 in 1937, and \$903 in 1936 (Table 1). The largest increases in 1939 were in feed and grain and in livestock. The increased value of feed and grain represented higher prices at the end of the year as well as larger quantities of grain on hand (Page i and Fig. 2). The average amounts of grain on hand in Area 3 at the two inventory periods follow:

	Beginning of year (bushels)	End of year (bushels)
Corn	4,278	5,257
Oats	834	716
Wheat	82	106
Soybeans	121	149

Cash receipts.--Cash receipts reached the highest level in four years, averaging, \$7,934 in 1939 (Table 1). Receipts from AAA, as well as from total productive livestock and feed and grain, were larger in 1939 than in 1938. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs.

Cash expenses. -- Cash expenses were larger in 1939 than in any of the last four years. The largest increases in expenditures were for cattle and feed and grain.

Earnings. -- Cash receipts exceeded cash expenses in 1939 by \$2,382 or by a slightly smaller margin than in 1938. Cash balance, the difference between these receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments, and savings.

The amounts deducted for operator's and family labor remained rather uniform during the 4-year period, a difference of only \$88 occurring between the low year, 1939, and the high year, 1937. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$50 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$3,501 in 1939 as contrasted with \$2,560 in 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm earnings. -- A wide variation was found in earnings on the farms in Area 3; for example, 62 farms earned less than 5 percent on the investment, with an average rate earned of 3.5 percent, but in contrast 40 farms earned 14 percent or more, with an average rate earned of 15.6 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had only \$45 left for labor and management earnings as contrasted with \$4,376 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the area was as follows:

Rate	Number	Average	Acres	Capital in-	Gross	Net	Labor and
earned on	of	rate	per	vested	earnings	earnings	management
investment	farms	earned	farm	per farm	per farm	per farm	earnings

Comparison of Farms According to Quality of Land

The 511 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms 275 had 85 percent or more of land area tillable, and 236 had less than 85 percent tillable. The average percent tillable was 93.0 for the former group and 68.3 for the latter group.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar quality of land as well as with the average of all accounting farms (Tables 2 and 3).

The capital investment averaged \$39,202, or \$174 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$36,101, or \$130 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases were \$434 larger, but the expenses and net decreases were \$73 smaller on farms of higher-quality land than on those of lower-quality land. Total productive livestock receipts and net increases were \$399 smaller for the farms with the larger percent of land area tillable; whereas, the grain receipts were \$787 larger. The rate earned on investment was 9.5 percent and 9.0 percent, and the labor and management earnings were \$2,300 and \$1,934, respectively, for the two groups of farms.

The farms on higher-quality land were 52 acres smaller than were those on lower-quality land; yet the former had 10 acres more land in crops. They also had a larger percent of tillable land in corn, oats, and soybeans but a smaller percent in wheat. The amount of livestock per farm was larger on the farms with the most untillable land, as indicated by the value of feed fed to productive livestock and the capital invested in productive livestock (Table 3).

CHART FOR STUDYING THE EFFICIENCY OF VARIOUS PARTS OF YOUR BUSINESS, FARMS WITH LESS THAN 85 PERCENT OF THE LAND AREA TILLABLE

Accounting Farms in Farming-Type Area 3, 1939

The numbers above the lines across the middle of the page are the averages for the 236 farms included in this group for the factors named at the top of the page. By drawing a line across each column at the number measuring the efficiency of your farm in that factor, you can compare your efficiency with that of other farmers in your locality.

larger crop yields per acre on the farms on higher-quality land, which amounted to 4.2 bushels of corn, 3.9 bushels of oats, 3.4 bushels of wheat, and 2.8 bushels of soybeans, indicate the relative productive level of the two groups of farms.

The operating expenses per acre averaged \$12.36 on the farms with the most tillable land and \$10.28 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$1.32 smaller on the farms with the larger percent of tillable land, but the combined cost per acre for improvements and taxes was \$.55 larger.

The livestock-efficiency factors, such as poultry returns per hen, hog returns per litter of pigs farrowed, and dairy returns per cow milked, were not appreciably affected by the quality of land. These factors indicate that the two groups of farms were operated with about the same degree of efficiency. Therefore, it may be assumed that the differences in organization, land use, crop yields, and costs were principally due to the differences in the productivity of the land on the two groups of farms.

Source of Income

The 511 farms were divided into six groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column in Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that generally the grain farms were located on the better land: high value of land per acre, large percent of land area tillable, large percent of land in grain, high yield of corn per acre, and land tax per acre.

The returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, according to 5-year averages of complete cost studies (1933-1937), are as follows: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the six groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. The amount of feed fed per acre to productive livestock averaged \$18.10 on the cattle farms but only \$5.24 on the grain farms.

Differences in expenses are significant for the six groups of farms. Labor input per crop acre was highest on the cattle farms, where 30.6 months of labor were used, and lowest on the grain farms, where 20.1 months of labor were used; horse and machinery cost per crop acre averaged \$11.82 on the dairy farms, \$6.07 on the cattle farms, \$5.61 on the hog farms, and only \$4.65 on the grain farms; improvement costs per acre ranged from \$1.03 on the general farms with the least livestock to \$2.11 on the dairy farms; and land taxes ranged from \$1.09 on the hog farms to \$1.18 on the grain farms.

Size of Farm as Related to Earnings

The farm records in Farming-Type Area 3, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 33 largest farms had labor and management earnings which averaged \$4,230 as contrasted with \$944 for the 56 smallest farms. The earnings, as measured by the rate earned on the investment, were slightly larger for the largest farms than for the smallest farms. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent) the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate earned averages less than the capitalization rate.

The smaller farms were operated more intensively than were the larger farms. This variation was indicated by the larger amount of feed fed per acre to productive livestock and by the larger number of months of labor per 100 crop acres.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. A tabulation of farm account records by counties and groups of counties indicates some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income (Tables 6 and 7).

In this report an average was calculated for each county from which 30 or more records were received. Averages were made in some instances with less than 30 records if it was necessary to eliminate some records because they were incomplete or not typical for the area. In any tabulation containing as few as 30 records, part of the variation from county to county is due to the fact that the averages do not represent a cross section of the county.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year even though these records are from farms with efficiency which is higher than average.

Influence of Price Changes on Illinois Farm Incomer

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even thou 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939: lairy cows, 2 percenter cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; broad sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1930 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were great at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Frices of important farm products. -- Prices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these prices eccurred during the last four months of the year.

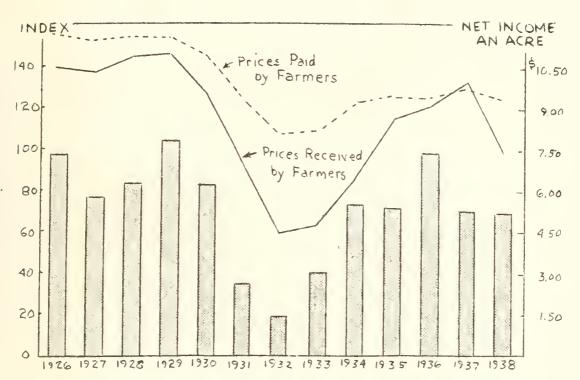

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

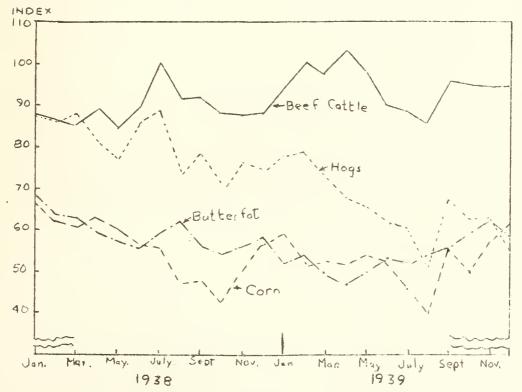

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 3 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and deiry products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and pats, 97.

Crop yields in all counties except Massac were above the lo-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low oat yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corn, oats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

FARM BUSINESS REPORT . . . 1939

FARMING-TYPE AREA FOUR East Central Cash Grain Area

DEPARTMENT OF AGRICULTURAL ECONOMICS, UNIVERSITY OF ILLINOIS

COLLEGE OF AGRICULTURE, EXTENSION SERVICE IN AGRICULTURE AND HOME ECONOMICS

URBANA, ILLINOIS

Annual Farm Business Report

ON FIVE HUNDRED FIFTY-NINE FARMS IN FARMING-TYPE AREA 4, 1939

By P. E. Johnston, J. B. Cunningham, and E. M. Hughes

Farm earnings of accounting farms in Farming-Type Area 4 were higher in 1939 than in 1938. The net earnings per acre averaged \$12.60 in 1939, \$9.67 in 1938, \$10.30 in 1937, and \$13.15 in 1936. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 4 Cash grain

Since the value of farm products used in the household was not included in the records prior to 1938, the earnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.01 in 1938 and \$.88 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

High crop yields and larger AAA payments, accompanied by increased industria activity and improved demand for farm products, especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes. -- The year 1939 was the fourth consecutive year of increasing inventories, the increases averaging \$1,417 in 1939, \$519 in 1938, \$1,029 in 1937, and \$853 in 1936 (Table 1). The largest increases in 1939 were in feed and grain. The increased value of feed and grain represented higher prices at the end of the year as well as larger quantities of grain on hand (Page i and Fig. 2). The average amounts of grain on hand in Area 4 at the two inventory periods follow:

	Beginning of year (bushels)	End of year (bushels)
Corn	4,281	5,241
Oats	740	582
Wheat	69	187
Soybeans	221	255

Cash receipts.--Cash receipts averaged \$6,643 in 1939 (Table 1). Feed and grain and AAA receipts were larger in 1939 than in 1938, but total productive livestock sales were smaller. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs.

Cash expenses. -- Cash expenses were larger in 1939 than in any of the last four years. Less money was spent for machinery in 1939 than in any other year of the last four years, although more was spent for productive livestock and feed and grain.

Earnings. -- Cash receipts exceeded cash expenses in 1939 by \$2,414. Cash balance, the difference between receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments, and savings.

The amounts deducted for operator's and family labor remained rather uniform during the 4-year period, a difference of only \$85 occurring between the low year, 1939, and the high year, 1936. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$50 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$3371 in 1939 as contrasted with \$2,544 in 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm earnings. -- A wide variation was found in earnings on the farms in Area 4; for example, 39 farms earned less than 4 percent on the investment, with an average rate earned of 2.4 percent, but in contrast 33 farms earned 13 percent or more, with an average rate earned of 14.8 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had a loss of \$208 for labor and management earnings as contrasted with a gain of \$4,021 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the areas was as follows:

				Capital			
Rate	Number	Average	Acres	in-	Gross	Net	Labor and

Comparison of Farms According to Quality of Land

The 559 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms, 326 had 93 percent or more of land area tillable, and 233 had less than 93 percent tillable. The average percent tillable was 96.1 for the former group and 83.6 for the latter group.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar quality of land as well as with the average of all accounting farms (Tables 2 and 3).

The capital investment averaged \$43,435, or \$166 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$37,025, or \$134 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases were \$789 larger and expenses and net decreases \$36 larger on farms of higher-quality land than on those of lower-quality land; the livestock receipts were \$356 smaller, whereas the grain receipts were \$1,068 larger. The rate earned on investment was 8.5 percent and 7.9 percent, and the labor and management earnings were \$2,046 and \$1,607, respectively, for the two groups of farms.

The farms on higher-quality land were 13 acres smaller than were those on lower-quality land; yet the former had 15 acres more land in crops. They also had a larger percent of tillable land in corn, oats, and soybeans but a smaller percent in wheat. The amount of livestock per farm, however, was larger on the farms with the lower-quality land, as indicated by the value of feed fed to productive livestock and the capital invested in productive livestock (Tables 2 and 3)

CHART FOR STUTYING THE EFFICIENCY OF VARIOUS DARTS OF YOUR SUSINESS, FARMS WITE MORE THAN 93 JERGENT OF THE LAND AREA TILLARDS

Accounting Farms in Farming-Type Area -, 1939

The numbers above the lines across the midile of the page are the averages for the 326 farms included in this group for the factors named at the top of the page. By drawing a line across each column at the number measuring the efficiency of your farm in that factor, you can compare your efficiency with that of other farmers in your locality.

^{1/} Includes farm share of automobile. 2/ Includes operator's and family labor.

Larger crop yields per acre on the farms on higher-quality land, which amounted to 3.1 bushels of corn, .4 bushels of oats, 1.9 bushels of wheat, and 3.3 bushels of soybeans, indicate the relative productive level of the two groups of farms.

The operating expenses per acre averaged \$10.73 on the farms with the most tillable land and \$10.01 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$.59 smaller on the farms with the larger percent of tillable land, but the combined cost per acre for improvements and taxes was \$.21 larger.

The livestock-efficiency factors, such as poultry returns per hen, hog returns per litter of pigs farrowed, and dairy returns per cow milked, were not appreciably affected by the quality of land. These factors indicate that the two groups of farms were operated with about the same degree of efficiency. Therefore, it may be assumed that the differences in organization, land use, crop yields, and costs were principally due to the differences in the productivity of the land on the two groups of farms.

Source of Income

The 599 farms were divided into 6 groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column in Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that generally the grain farms were located on the better land: high value of land per acre, large percent of land area tillable, large percent of land in grain, and high yield of corn per acre.

The returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, according to 5-year averages of complete cost studies (1933-1937), are as follows: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the 6 groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. The amount of feed fed per acre to productive livestock averaged \$14.27 on the cattle farms but only \$3.65 on the grain farms.

Differences in expenses are significant for the 6 groups of farms. Labor input was highest on the cattle farms, where 27.5 months of labor were used, and lowest on the grain and hog farms, where 21.1 months of labor were used. Horse and machinery cost per crop acre averaged \$7.57 on the dairy farms, \$5.28 on the hog farms, \$4.65 on the cattle farms, and only \$4.33 on the grain farms. Improvement cost per acre ranged from \$.88 on the grain farms to \$1.36 on the hog farms; and land taxes ranged from \$1.17 on the cattle farms to \$1.32 on the hog farms.

Size of Farm as Related to Earnings

The farm records in Farming-Type Area 4, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 55 largest farms had labor and management earnings which averaged \$3,837 as contrasted with \$731 for the 46 smallest farms. The earnings, as measured by the rate earned on the investment, were 9.0 percent, and 6.4 percent, respectively for these two groups of farms. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent) the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate earned averages less than the capitalization rate.

The smaller farms were operated more intensively than were the larger farms. This variation was indicated by the higher gross earnings per acre and by the larger amount of feed fed per acre to productive livestock.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. A tabulation of farm account records by counties and groups of counties indicates some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income (Tables 6 and 7).

In this report an average was calculated for each county from which 30 or more records were received. Averages were made in some instances with less than 30 records if it was necessary to eliminate some records because they were incomplete or not typical for the area. In any tabulation containing as few as 30 records, part of the variation from county to county is due to the fact that the averages do not represent a cross section of the county.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year even though these records are from farms with efficiency which is higher than average.

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1, 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even though 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939: dairy cows, 2 percent beef cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were greate at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Frices of important farm products. -- Prices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these pricincreases occurred during the last four months of the year.

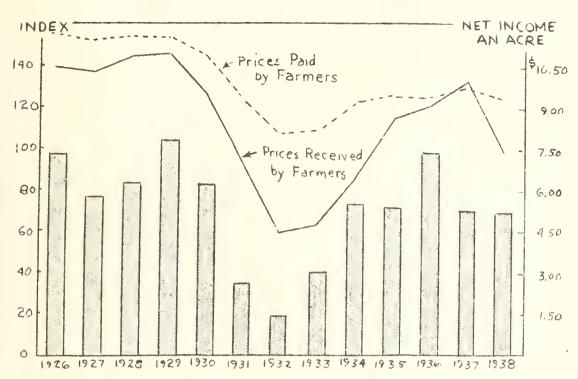

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

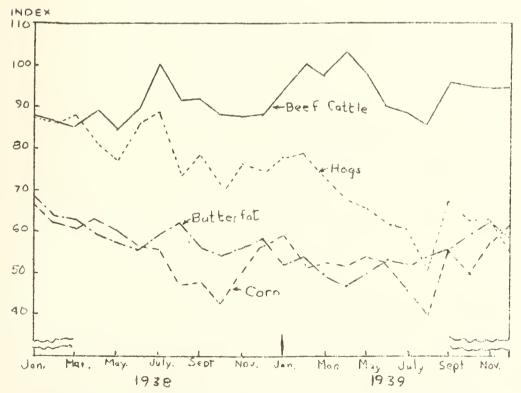

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 5 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs aropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and pats, 97.

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low oat yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corn, oats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

FARM BUSINESS REPORT . . . 1939

FARMING-TYPE AREA FIVE West Central General Farming Area

DEPARTMENT OF AGRICULTURAL ECONOMICS, UNIVERSITY OF ILLINOIS

COLLEGE OF AGRICULTURE, EXTENSION SERVICE IN AGRICULTURE AND HOME ECONOMICS

URBANA, ILLINOIS

Annual Farm Business Report

ON THREE HUNDRED FIFTEEN FARMS IN FARMING-TYPE AREA 5, 1939

By P. E. Johnston, J. B. Cunningham, and E. M. Hughes 1

Farm earnings of accounting farms in Farming-Type Area 5 were higher in 1939 than in 1938. The net earnings per acre averaged \$9.77 in 1939, \$7.93 in 1938, \$8.21 in 1937, and \$7.72 in 1936. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 5 General Farming

Since the value of farm products used in the household was not included in the records prior to 1938, the earnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.15 in 1938 and \$.98 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

High crop yields and more livestock, accompanied by increased industrial activity and improved demand for farm products especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

^{1/}R. J. Mutti supervised the closing of the farm accounts and the preparation of the tables used in this report. The farm accounts project was conducted in cooperation with the farm bureaus in the following counties and was supervised by the farm advisers indicated:

W. F. Coolidge, Morgan County

W. S. Batson, Shelby County

G. B. Whitman, Adams County

O. O. Mowery, Macoupin County

C. S. Love, Christian County

W. F. Purnell, Greene County

A. E. Snyder, Montgomery County

C. T. Kibler, Jersey County

R. T. Nicholas, Schuyler County

W. B. Bunn, Pike County

G. H. Reid, Scott County

E. H. Garlich, Brown County

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes.--The year 1939 was the fourth consecutive year of increasing inventories, the increases averaging \$1,108 in 1939, \$517 in 1938, \$857 in 1937, and \$687 in 1936 (Table 1). The largest increases in 1939 were in feed and grain and in livestock. The increased value of feed and grain represented higher prices at the end of the year as well as larger quantities of grain on hand (Page 1 and Fig. 2). The average amounts of grain on hand in Area 5 at the two inventory periods follow:

	Beginning of year (bushels)	End <u>of year</u> (bushels)
Corn	2,609	3,033
Oats	436	353
Wheat	122	220
Soybeans	104	130

Cash receipts. Cash receipts reached the highest level in four years, averaging \$6,194 in 1939 (Table 1). Total productive livestock, grain, and AAA payments were larger in 1939 than in 1938. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs.

Cash expenses. Cash expenses were also larger in 1939 than in any of the last four years. Every cash expense item, except horses, was larger in 1939 than in 1938. The largest increase in expenditures was for cattle, the purchases averaging \$976 in 1939 and \$565 in 1938.

Earnings. Cash receipts exceeded cash expenses by \$1,958 in 1939. Cash balance, the difference between these receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments, and savings.

The amounts deducted for operator's and family labor remained rathor uniform during the 4-year period, a difference of only \$23, occurring between the low year, 1938, and the high year, 1936. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$50 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$2,553 in 1939 as contrasted with \$1,918 for 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm earnings. -- A wide variation was found in earnings on the farms in Area 5; for example, 26 farms earned less than 3 percent on the investment, with an average rate earned of 1.1 percent; but in contrast, 25 farms earned 15 percent or more, with an average rate earned of 17.9 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had a loss of \$310 for labor and management earnings as contrasted with a gain of \$4,152 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the areas was as follows:

Rate earned on investment (percent)	Number of farms	Average rate earned (percent)	Acres per farm	Capital in- vested per farm	Gross earnings per farm	Net earnings per farm	Labor and management earnings
Less than 3 3.0 to 6.9 7.0 to 10.9 11.0 to 14.0 15.0 or more	74 121 9 69	1.1 5.4 8.8 12.6 17.9	236 265 266 252 280	\$21,179 29,293 30,391 26,533 28,414	\$2,916 4,250 5,307 5,923 8,300	\$ 236 1,570 2,679 3,347 5,073	\$ -310 627 1,683 2,561 4,152

Comparison of Farms According to Quality of Land

The 315 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms, 156 had 85 percent or more of land area tillable, and 159 had less than 85 percent tillable. The average percent tillable was 93.7 for the former group and 65.7 for the latter group.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar quality of land as well as with the average of all accounting farms (Tables 2 and 3).

The total capital investment averaged \$31,476 per farm, or \$130 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$25,325, or \$90 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases were \$947 larger, and expenses and net decreases \$253 larger, on farms of higher quality land than on those of lower quality land. The livestock receipts were \$182 smaller for the farms with the larger percent of land area tillable, whereas the grain receipts were \$1,101 larger. The rate earned on investment was 9.2 percent and 8.8 percent and the labor and management earnings \$1,866 and \$1,456, respectively, for the two groups of farms.

The farms of higher quality land were 38 acres smaller than those on lower quality land; yet the former has 34 acres more land in crops. They also had a larger percent of tillable land in soybeans and in hay and pasture but a smaller percent in other crops. The amount of livestock per farm was practically the same for the two groups of farms as indicated by the value of feed fed to productive livestock (Table 3).

Larger crop yields per acre on the farms on higher quality land, which amounted to 1.4 bushels of corn, 3.1 bushels of oats, 2.6 bushels of wheat, and 4.8 bushels of soybeans, indicate the relative productive level of the two groups of farms.

The operating expenses per acre averaged \$10.82 on the farms with the most tillable land and \$8.39 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$1.18 smaller on the farms with the larger percent of tillable land, but the combined cost per acre for improvements and taxes was \$.55 larger.

The livestock-efficiency factors, such as poultry returns per hen, hog returns per litter of pigs farrowed, and dairy returns per cow milked, were not appreciably affected by the quality of land. These factors indicate that the two groups of farms were operated with about the same degree of efficiency. Therefore, it may be assumed that the differences in organization, land use, crop yields, and costs were principally due to the differences in the productivity of the land on the two groups of farms.

Source of Income

The 315 farms were divided into 6 groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column of Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms, the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that generally the grain farms were located on the better land: high value of land per acre, large percent of land area tillable, large percent of land in grain, and high taxes per acre.

According to 5-year averages (1933-1937) of complete cost studies the returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, are as follows: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the six groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. The amount of feed fed per acre to productive livestock averaged \$12.58 on the cattle farms but only \$4.25 on the grain farms.

Differences in expenses are significant for the six groups of farms. Labor input was highest on the cattle farms, where 28.3 months of labor were used, and lowest on the general farms with least livestock, where 22.1 months of labor were used. Horse and machinery cost per crop acre averaged \$7.02 on the dairy farms, \$4.81 on the cattle farms, \$4.55 on the hog farms, and only \$4.37 on the grain farms. Improvement costs per acre ranged from \$.70 on the grain farms to \$.99 on the general livestock farms. Taxes ranged from \$.69 on the dairy farms to \$1.12 on the grain farms.

Size of Farm As Related to Earnings

The farm records in Farming-Type Area 5, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 38 largest farms had labor and management earnings which averaged \$2,498 as contrasted with \$925 for the 27 smallest farms. The earnings, as measured by the rate carned on the investment, averaged slightly higher, however, for the middle-sized farms than for either the largest or the smallest farms. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent), the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate earned averages less than the capitalization rate.

The smaller farms were operated more intensively than were the larger farms. This variation was indicated by the much higher gross earnings per acre, by the larger proportion of total land tillable, by the higher investments per acre, by the larger amount of feed fed per acre to productive livestock, and by the larger amount of labor used per 100 crop acres.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. A tabulation of farm account records by counties and groups of counties indicates some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income (Tables 6 and 7).

In this report an average was calculated for each county from which 30 or more records were received. Averages were made in some instances with less than 30 records if it was necessary to eliminate some records because they were incomplete or not typical for the area. In any tabulation containing as few as 30 records, part of the variation from county to county is due to the fact that the averages do not represent a cross section of the county.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year, even though these records are from farms with efficiency which is higher than average.

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1, 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even though 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939; dairy cows, 2 percent; beef cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood cows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were great at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Frices of important farm products. -- Prices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these price increases occurred during the last four menths of the year.

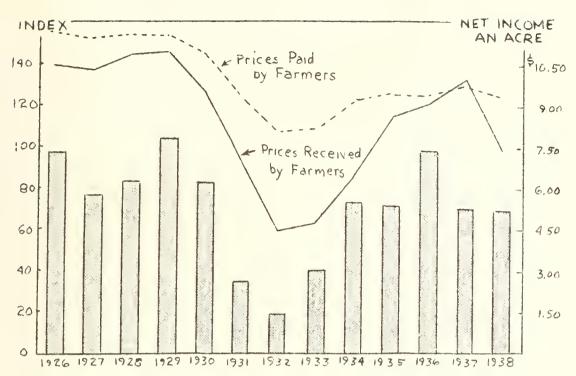

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

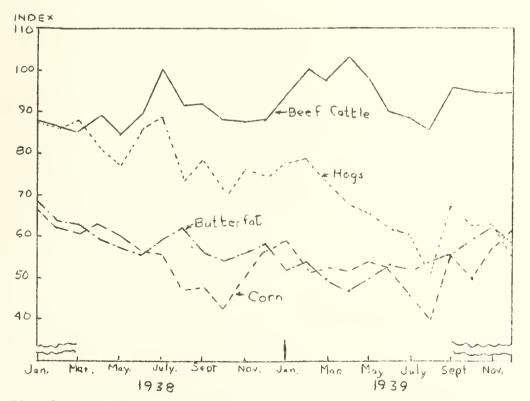

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 5 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: cats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and pats, 97.

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low oat yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

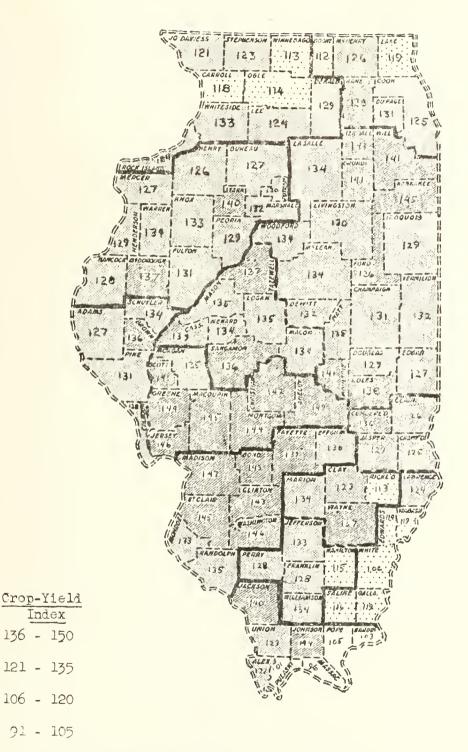

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the game county. The indices are based on county yields of corn, cats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

FARM BUSINESS REPORT . . . 1939

FARMING-TYPE AREA SIX St. Louis Dairy and Wheat Area

DEPARTMENT OF AGRICULTURAL ECONOMICS, UNIVERSITY OF ILLINOIS
COLLEGE OF AGRICULTURE, EXTENSION SERVICE IN AGRICULTURE AND HOME ECONOMICS
URBANA, ILLINOIS

Annual Farm Business Report

ON TWO HUNDRED SEVENTY-ONE FARMS IN FARMING-TYPE AREA 6, 1939

By P. E. Johnston, J. B. Cunningham, and E. N. Searls 1

Farm earnings of accounting farms in Farming-Type Area 6 were higher in 1939 than in 1938. The average net earnings per acre were \$7.96 in 1939, \$5.11 in 1938, \$6.17 in 1937, and \$5.84 in 1936. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 6
Wheat, Dairy and Poultry

Since the value of farm products used in the household was not included in the records prior to 1938, the earnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.39 in 1938 and \$1.31 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

High crop yields and more livestock, accompanied by increased industrial activity and improved demand

for farm products especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes. -- The year 1939 was the fourth consecutive year of increasing inventories, the increases averaging \$597 in 1939, \$182 in 1938, \$615 in 1937, and \$500 in 1936 (Table 1). The largest increases in 1939 were in feed and grain and in livestock. The increased value of feed and grain represented higher prices at the end of the year as well as larger quantities of grain on hand (Page i and Fig. 2). The average amounts of grain on hand in Area 6 at the two inventory periods follow:

	Beginning of year (bushels)	End of year (bushels)
Corn	940	1217
Oats	271	274
Wheat	260	267
Soybeans	25	25

Cash receipts. Cash receipts reached the second highest level in four years, averaging \$3,649 in 1939. Feed and grain and AAA receipts were larger in 1939 than in 1938, but productive livestock sales were smaller. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs. (Table 1).

Cash expenses. Cash expenses were lower in 1939 than in either 1938 or 1937, but they were higher in 1939 than in 1936. Less money was spent for improvements, machinery, and crop expenses in 1939 than in 1938, although more was spent for productive livestock, feed and grain, labor, livestock expense, and taxes.

Earnings. Cash receipts exceeded cash expenses in 1939 by \$1,423, or by a larger margin than that for any other year during the past four years. Cash balance, the difference between these receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments, and savings.

The amounts deducted for operator's and family labor remained rather uniform during the 4-year period, a difference of only \$29 occurring between the low year, 1939, and the high year, 1936. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$40 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$1,606 in 1939 as contrasted with \$1,061 for 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm carnings. -- A wide variation was found in carnings on the farms in Area 6; for example, 30 farms carned less than 3 percent on their investment, with an average rate earned of less than 1 percent, but in contrast 33 farms earned 15 percent or more, with an average rate earned of 18 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had a loss of \$117 for labor and management earnings as contrasted with a gain of \$2,441 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the areas was as follows:

Rate earned on investment (percent)	Number of farms	Average rate earned (percent)	Acres per farm	Capital in- vested per farm	Gross earnings per farm	Net earnings per farm	Labor and management earnings
Less than 3.	0 30	.9	174	\$12,980	\$1,796	\$ 116	\$ -117

11.0 to 14.9	52	12.8	196	18,239	4,505	2,334	1,857
15 or more	33	18.2	189	15,158	4,594	2,761	2,441

Comparison of Farms According to Quality of Land

The 271 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms 132 had 85 percent or more of land area tillable, and 139 had less than 85 percent tillable. Thus, the average percent tillable was 92.6 for the former group and 68.8 for the latter group.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar quality of land as well as with the average of all accounting farms (Tables 2 and 3).

The capital investment averaged \$18,104, or \$97 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$16,709, or \$77 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases were \$362 larger on farms of higher quality land than on those of lower quality land, and expenses and net decreases were \$62 larger. The livestock receipts were \$214 smaller for the farms with the larger percent of land area tillable, whereas the grain receipts were \$548 larger. The rate earned on investment was 9.8 percent and 8.6 percent, respectively, for the two groups of farms, and the labor and management earnings were \$1,306 and \$1,034.

The farms on higher quality land were 30 acres smaller than those on lower quality land; yet the former had 20 acres more land in crops. They also had a larger percent of tillable land in grain crops but a smaller percent in hay and pasture. The amount of livestock per farm was practically the same for the two groups of farms as indicated by the value of feed fed to productive livestock and the capital invested in productive livestock (Table 4).

CHART FOR STUDYING THE EFFICIENCY OF VARIOUS PARTS OF YOUR BUSINESS, ON FARMS WITH MORE THAN 85 PERCENT OF THE LAND AREA TILLABLE

Accounting Farms in Farming-Type Area 6, 1939

The numbers above the lines across the middle of the page are the averages for the 132 farms included in this group for the factors named at the top of the page. By drawing a line across each column at the number measuring the efficiency of your farm in that factor, you can compare your efficiency with that of other farmers in your locality.

I/ Includes farm share of automobile.
2/ Includes operator's and family labor.
3/ Includes several large and specialized hog farms.

Larger crop yields per acre on the farms on higher quality land, which amounted to 5 bushels of corn, 1.7 bushels of wheat, and 1.7 bushels of soybeans, indicate the relative productive level of the two groups of farms.

The operating expenses per acre averaged \$9.77 on the farms with the most tillable land and \$8.79 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$1.89 smaller on the farms with the larger percent of tillable land, although the combined cost per acre for improvements and taxes was \$.27 larger.

The livestock-efficiency factors, such as poultry returns per hen, hog returns per litter of pigs farrowed, and dairy returns per cow milked, were not appreciably affected by the quality of land. These factors indicate that the two groups of farms were operated with about the same degree of efficiency. Therefore, it may be assumed that the differences in organization, land use, crop yields, and costs were principally due to the differences in the productivity of the land on the two groups of farms.

Source of Income

The 271 farms were divided into six groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column of Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that generally the grain farms were located on the better land: high value of land per acre, large percent of land area tillable, large percent of land in grain, and high yield of corn per acre.

The returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, according to 5-year averages of complete cost studies (1933-1937), follow: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the six groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. The amount of feed fed per acre to productive livestock averaged \$16.36 on the hog farms but only \$3.51 on the grain farms.

Differences in expenses are significant for the six groups of farms. Labor input was highest on the truck farms, where 30.7 months of labor were used, and lowest on the hog farms, where 19.2 months of labor were used; horse and machinery cost per crop acre averaged \$6.57 on the truck farms, \$6.24 on the hog farms, \$5.86 on the dairy farms, and only \$3.89 on the grain farms; improvement costs per acre ranged from \$1.32 on the hog farms to \$.52 on the grain farms; and land taxes ranged from \$1.21 on the truck farms to \$.62 on the dairy farms.

Size of Farm As Related to Earnings

The farm records in Farming-Type Area 6, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 11 largest farms had labor and management earnings which averaged \$1,659 as contrasted with \$878 for the 48 smallest farms. The earnings, as measured by the rate earned on the investment, were slightly higher, however, for the smaller farms than for the larger ones. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent) the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate earned averages less than the capitalization rate.

The smaller farms were operated more intensively than were the larger farms. This variation was indicated by the much higher gross and net earnings per acre, by the larger proportion of total land tillable, by the higher land values, by the larger amount of feed fed per acre to productive livestock, and by the substantially higher crop yields.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. A tabulation of farm account records by counties and groups of counties indicates some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income (Tables 6 and 7).

In this report an average was calculated for each county from which 30 or more records were received. Averages were made in some instances with less than 30 records if it was necessary to eliminate some records because they were incomplete or not typical for the area. In any tabulation containing as few as 30 records, part of the variation from county to county is due to the fact that the averages do not represent a cross section of the county.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year even though these records are from farms with efficiency which is higher than average.

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1, 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even though 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939; dairy cows, 2 percent; beef cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were greater at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Frices of important farm products. -- Prices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these price increases occurred during the last four months of the year.

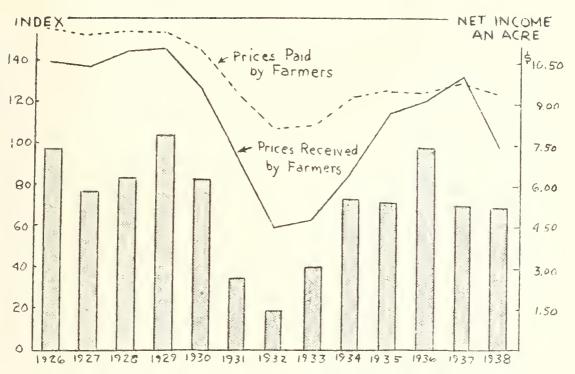

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

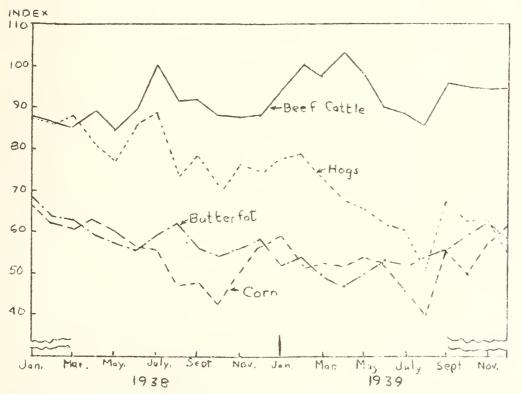

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm. products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 3 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and pats, 27.

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low oat yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corn, cats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

FARM BUSINESS REPORT . . . 1939

FARMING-TYPE AREA SEVEN South Central Mixed Farming Area

DEPARTMENT OF AGRICULTURAL ECONOMICS, UNIVERSITY OF ILLINOIS

COLLEGE OF AGRICULTURE, EXTENSION SERVICE IN AGRICULTURE AND HOME ECONOMICS

URBANA, ILLINOIS

Annual Farm Business Report

ON ONE HUNDRED THREE FARMS IN FARMING-TYPE AREA 7, 1939

By P. E. Johnston, J. B. Cunningham, and E. N. Searls 1

Farm earnings of accounting farms in Farming-Type Area 7 were higher in 1939 than in 1938. The net earnings per acre averaged \$4.30 in 1939, \$3.71 in 1938, \$3.48 in 1937, and \$4.97 in 1936. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 7
Mixed Farming

Since the value of farm products used in the household was not included in the records prior to 1938, the earnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.24 in 1938 and \$1.12 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

High crop yields and more livestock, accompanied by increased industrial activity and improved demand for farm products especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

LY R. J. Mutti supervised the closing of the farm accounts and the preparation of the tables used in this report. The farm accounts project was conducted in cooperation with the farm bureaus in the following counties and was supervised by the farm advisers indicated:

W. L. Sidwell, Jefferson County

R. L. Ash, Clark County

R. E. Apple, Jasper County

Harold Allison, Crawford County

F. J. Blackburn, Marion County Dee Small, Williamson County

C. L. Beatty, Richland County

R. K. Wise, Clay County

J. A. Embser, Franklin-Hamilton Counties

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes. -- The year 1939 was the fourth consecutive year of increasing inventories, the increases averaging \$407 in 1939, \$229 in 1938, \$461 in 1937, and \$458 in 1936 (Table 1). The largest increases in 1939 were in feed and grain and in livestock. The increased value of feed and grain represented higher prices at the end of the year as well as larger quantities of grain on hand (Page 1 and Fig. 2). The average amounts of grain on hand in Area 7 at the two inventory periods follow:

	Beginning of year (bushels)	End of year (bushels)		
Corn	1,140	1,260		
Oats	147	180		
Wheat	109	73		
Soybeans	33	30		

Cash receipts. Cash receipts averaged \$2,940 in 1939 and were about the same as in 1938 (Table 1). Feed and grain and AAA receipts were larger in 1939 than in 1938, but livestock sales were smaller. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs.

Cash expenses. Cash expenses were lower in 1939 than in either 1938 or 1937, but they were higher in 1939 than in 1936. Less money was spent for livestock, feed and grain, hired labor, crop expense, and taxes in 1939 than in 1938, but more was spent for farm improvements and horses.

Earnings. Cash receipts exceeded cash expenses in 1939 by \$969, or by a larger margin than that for any year since 1936. Cash balance, the difference between these receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments, and savings.

The amounts deducted for operator's and family labor remained rather uniform during the 4-year period, a difference of only \$22 occurring between the low year, 1938, and the high year, 1939. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$40 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$976 in 1939 as contrasted with \$802 for 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm earnings. -- A wide variation was found in earnings on the farms in Area 7; for example, 13 farms earned less than 1 percent on the investment, with an average rate earned of -1.4 percent; but in contrast 14 farms earned 13 percent or more, with an average rate earned of 18.4 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had a loss of \$160 for labor and management earnings as contrasted with a gain of \$1,788 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the area was as follows:

Rate earned on investment (percent)	Number of farms	Average rate earned (percent)	Acres per farm	Capital in- vested per farm	Gross earnings per farm	Net earnings per farm	Labor and management earnings
Less than 1 1.0 to 4.9 5.0 to 8.9 9.0 to 12.9 13.0 or more	24 32 20	-1.4 3.1 6.9 10.4 18.4	166 214 254 246 216	\$ 8,584 15,653 16,517 13,112 10,285	\$1,362 2,496 3,084 2,940 3,500	\$ -118 490 1,142 1,364 1,890	\$ -160 181 714 1,156 1,788

Comparison of Farms According to Percent of Land Area Tillable

The 103 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms, 54 had 85 percent or more of land area tillable, and 49 had less than 85 percent tillable. The average percent tillable was 91.3 for the former group and 73.5 for the latter group.

There was a tendency for the farms with the larger percent of land area tillable to have low-producing gray prairie soil and for the farms with the smaller percent of land area tillable to have rough land associated with small areas of high-producing bottomland.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar proportion of tillable land as well as with the average of all accounting farms (Tables 2 and 3).

The capital investment averaged \$12,245, or \$56 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$15,527, or \$65 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases were \$144 smaller and expenses and net decreases \$64 smaller on farms with the larger percent of land area tillable than on those with the smaller percent tillable. The livestock receipts were \$199 smaller for the farms with the larger percent of land area tillable, whereas the grain receipts were \$75 larger. The rate earned on investment was 7.5 percent and 6.7 percent, and the labor and management earnings were \$721 and \$701 respectively, for the two groups of farms.

2/ Includes operator's and family labor.

The farms with the larger percent of land area tillable were 21 acres smaller; yet they had ll acres more land in crops than did those farms with the smaller percent of land area tillable. Oat and wheat yields were higher but corn yields were lower on the farms with the higher percent tillable than on those with the lower percent tillable. In this farming-type area the flat prairie land, a large percent of which is tillable, is often low in productivity.

The operating expenses per acre averaged \$7.36 on the farms with the most tillable land and \$6.75 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$.98 smaller on the farms with the larger percent of tillable land, but the combined cost per acre for improvements and taxes was \$.12 larger.

The livestock-efficiency factors, such as poultry returns per hen, hog returns per litter of pigs farrowed, and dairy returns per cow milked, were not appreciably affected by the percent of land area tillable. These factors indicate that the livestock on the two groups of farms was managed with nearly the same degree of efficiency.

Source of Income

The 103 farms were divided into 4 groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column of Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that generally the grain farms were located on the better land: large percent of land area tillable, large percent of land in grain, and high yield of corn and wheat per acre.

The returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, according to 5-year averages of complete cost studies (1933-1937), are as follows: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the 4 groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. The amount of feed fed per acre to productive livestock averaged \$7.33 on the hog farms but only \$2.74 on the grain farms.

Differences in expenses are significant for the 4 groups of farms. Labor input was highest on the general farms with the most livestock, where 21.3 months of labor were used, and lowest on the grain farms, where 17.0 months of labor were used; horse and machinery cost per crop acre averaged \$4.41 on the general farms with the most livestock, \$4.05 on the hog farms, and only \$3.10 on the grain farms; improvement costs per acre ranged from \$1.06 on the general farms with the most livestock to \$.35 on the grain farms; and land taxes ranged from \$.47 on the grain farms to \$.59 on the hog farms.

Size of Farm as Related to Earnings

The farm records in Farming-Type Area 7, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 18 largest farms had labor and management earnings which averaged \$1,233 as contrasted with \$511 for the 36 smallest farms. The earnings, as measured by the rate earned on the investment, were 8.3 and 6.5, respectively, for the two groups of farms. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent), the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate earned averages less than the capitalization rate.

The smaller farms were operated more intensively than were the larger farms. This variation was indicated by the much higher gross earnings per acre, and by the larger amount of feed fed per acre to productive livestock.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. A tabulation of farm account records by counties and groups of counties indicates some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income (Tables 6 and 7).

In this report an average was calculated for each county from which 30 or more records were received. Averages were made in some instances with less than 30 records if it was necessary to eliminate some records because they were incomplete or not typical for the area. In any tabulation containing as few as 30 records, part of the variation from county to county is due to the fact that the averages do not represent a cross section of the county.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year even though these records are from farms with efficiency which is higher than average.

Influence of Trice Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Aijustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even the 62 million bushels of 1937 and 1938 corn were placed under seal at the end of th year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The fol lowing data indicate the percentage increase in livestock numbers on 2520 accouning farms in Illinois from the beginning to the end of 1939: dairy cows, 2 percenter cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brooksows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs 28 percent. Hog numbers have been increasing sinct 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beet cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were grea at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Frices of important farm products. -- Frices for all crops as well as for boef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these princreases occurred during the last four months of the year.

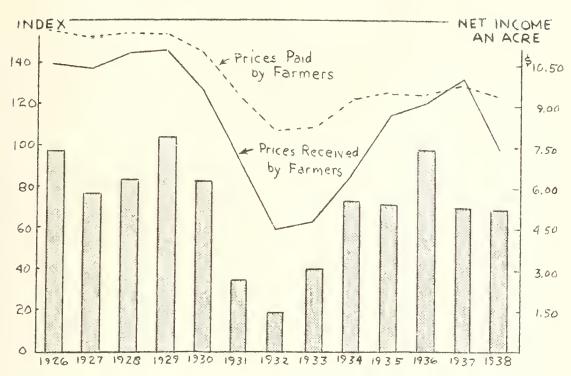

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

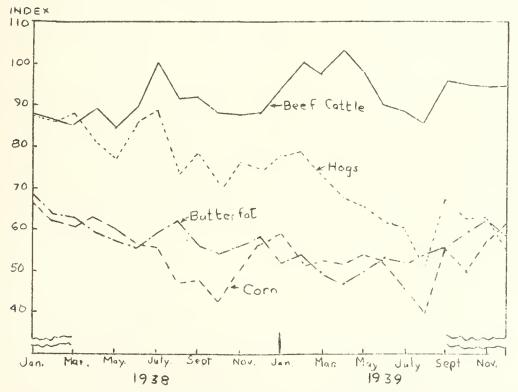

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 5 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and pata, 97.

Crop yields in all counties except Massac were above the 10-year average (1729-1738 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low out yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

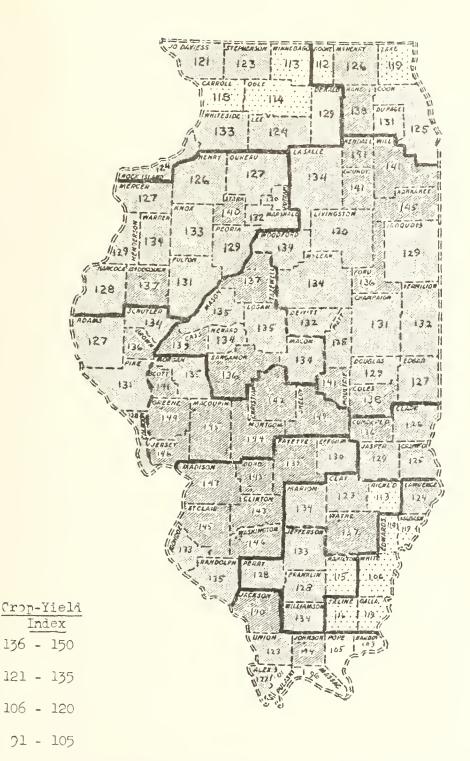

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corn, oats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

URBANA, ILLINOIS

Annual Farm Business Report

ON SIXTY-THREE FARMS IN FARMING-TYPE AREA 8, 1939

By P. E. Johnston, J. B. Cunningham, and E. N. Searls 1

Farm earnings of accounting farms in Farming-Type Area 8 were higher in 1939 than in 1938. The net earnings per acre averaged \$6.14 in 1939, \$4.55 in 1938, \$6.12 in 1937, and \$7.47 in 1936. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 8 Grain and Livestock

Since the value of farm products used in the household was not included in the records prior to 1938, the earnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.24 in 1938 and \$1.10 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

Moderately high crop yields and larger AAA receipts, accompanied by increased industrial activity and improved demand for farm products, especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

^{1/} R. J. Mutti supervised the closing of the farm accounts and the preparation of the tables used in this report. The farm accounts project was conducted in cooperation with the farm bureaus in the following counties and was supervised by the farm advisers indicated:

W. D. Murphy, Edwards County Thurman Wright, White County H. C. Wheeler, Lawrence County

H. H. Lett, Wabash County

R. H. Roll, Gallatin County

H. C. Neville, Saline County

^{1/} Includes farm share of automobile for 1936 and 1937. 2/ Not included as income for 1936 and 1937.

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes. -- The year 1939 was the fourth consecutive year of increasing inventories, the increases averaging \$185 in 1939, \$140 in 1938, \$457 in 1937, and \$620 in 1936 (Table 1). The largest increase in 1939 was in livestock; feed and grain, on the other hand, decreased in value despite higher prices at the end of the year as compared with those at the beginning (page i). The average amounts of grain on hand in Area 8 at the two inventory periods follow:

	Beginning of year (bushels)	End of year (bushels)
Corn	1467	1172
Oats	135	150
Wheat	100	66
Soybeans	67	57

Cash receipts. -- Cash receipts averaged \$3,444 in 1939 (Table 1). Feed and grain and AAA receipts were larger in 1939 than in 1938, but total productive livestock sales were smaller. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs.

Cash expenses. -- Cash expenses were slightly larger in 1939 than in 1938, but they were smaller in 1939 than in either 1937 or 1936. Less money was spent for total productive livestock, machinery, and labor in 1939 than in 1938, although slightly more was spent for feed and grain, automobile, and taxes.

Earnings. Cash receipts exceeded cash expenses in 1939 by \$1,470, or by a larger margin than that for any other year during the past four years except 1937. Cash balance, the difference between these receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments, and savings.

The amounts deducted for operator's and family labor remained rather uniform during the 4-year period, a difference of only \$46 occurring between the low year, 1938, and the high year, 1939. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$40 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$1,336 in 1939 as contrasted with \$928 for 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm earnings. -- A wide variation was found in earnings on the farms in Area 8; for example, 18 farms earned less than 5 percent on the investment, with an average rate earned of 2.3 percent, but in contrast 12 farms earned 11 percent or more, with an average rate earned of 14.4 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had \$167 for labor and management earnings as contrasted with a gain of \$2,136 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the areas was as follows:

Rate earned on investment (percent)	Number of farms	Average rate earned	Acres per farm	Capital in- vested per farm	Gross earnings per farm	Net earnings per farm	Labor and management earnings
Less than 5 5 to 11 11 or more	18	2.3	184	\$10,612	\$1,674	\$ 249	\$ 167
	33	8.1	226	18,152	3,209	1,475	963
	12	14.4	246	17,961	4,320	2,584	2,136

Comparison of Farms According to Quality of Land

The 63 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms, 30 had 90 percent or more of land area tillable, and 33 had less than 90 percent tillable. The average percent tillable was 94.6 for the former group and 78.1 for the latter group.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar quality of land as well as with the average of all accounting farms (Tables 2 and 3).

The capital investment averaged \$18,257, or \$78 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$13,874, or \$68 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases were \$1,097 larger and expenses and net decreases \$209 larger on farms of higher-quality land than on those of lower quality land. Cattle and dairy sales were smaller for the farms with the larger percent of land area tillable; whereas feed and grain, AAA, and hog receipts were larger. The rate earned on investment was 10.0 percent and 6.4 percent and the labor and management earnings were \$1,342 and \$611, respectively, for the two groups of farms.

The farms on higher-quality land were 29 acres larger and had 58 acres more land in crops than did those on lower-quality land. The farms with the higher quality land also had a larger percent of tillable land in grain crops but a smaller percent in hay and pasture. However, the amount of livestock per farm was larger on that group of farms having the smaller percent of land area tillable, as indicated by the value of feed fed to productive livestock and the capital invested in productive livestock (Tables 2 and 3).

Crop yields per acre for the two major grain crops were larger on the farms with the larger percent of land area tillable, the difference amounting to .6 bushel of corn and 3.8 bushels of wheat. Yields of oats, however, averaged 1.7 bushels lower on this group of farms than on the farms with the smaller percent of land area tillable.

The operating expenses per acre averaged \$6.97 on the farms with the most tillable land and \$7.22 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$2.78 smaller on the farms with the larger percent of tillable land, and the combined cost per acre for improvements and taxes was practically the same for the two groups of farms.

The farms with the higher percent of land area tillable had larger average poultry returns per hen and larger returns per litter of pigs farrowed but smaller dairy returns per cow.

Source of Income

The 63 farms were divided into 3 groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column of Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that generally the grain farms were located on the better land: high value of land per acre, large percent of land area tillable, large percent of land in grain, high yield of corn per acre, and land tax per acre.

The returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, according to 5-year averages of complete cost studies (1933-1937), are as follows: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the 3 groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. The amount of feed fed per acre to productive livestock averaged \$6.74 on the general farms with the most livestock but only \$2.43 on the grain farms.

Differences in expenses are significant for the 3 groups of farms. Labor cost per crop acre was highest on the general farms with the most livestock and lowest on the grain farms. Horse and machinery cost per crop acre averaged \$4.07 on the general farms with the most livestock, \$3.30 on the general farms with the least livestock, and only \$2.98 on the grain farms. Improvement cost per acre ranged from \$.65 on the farms with 60 percent or more of the income from livestock to \$.40 on the grain farms, and land taxes ranged from \$.63 on the former group of farms to \$.82 on the latter.

Size of Farm As Related to Earnings

The farm records in Farming-Type Area 8, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 12 largest farms had labor and management earnings which averaged \$1748 as contrasted with \$597 for the 32 smallest farms. The earnings, as measured by the rate earned on the investment, were also larger for the 12 largest farms. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent), the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate earned averages less than the capitalization rate.

The smaller farms were operated more intensively than were the larger farms. This variation was indicated by the higher gross earnings per acre, by the larger amount of feed fed per acre to productive livestock, and by the months of labor per 100 crop acres.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. A tabulation of farm account records by counties and groups of counties indicates some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income (Tables 6 and 7).

In this report an average was calculated for Edwards county from which 30 records were received. In any tabulation containing a small number of records, part of the variation from county to county is due to the fact that the averages do not represent a cross section of the county.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year even though these records are from farms with efficiency which is higher than average.

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even thou 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939: dairy cows, 2 percenter cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were great at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Frices of important farm products. -- Prices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these pri increases occurred during the last four months of the year.

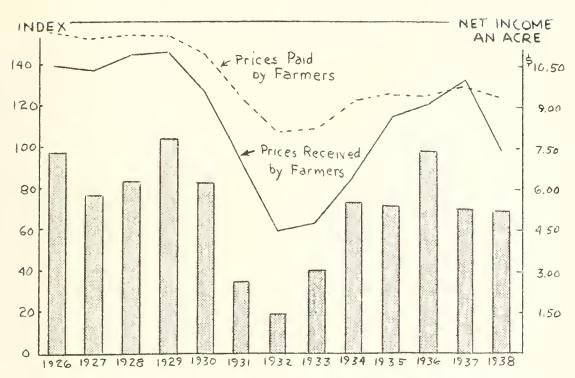

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

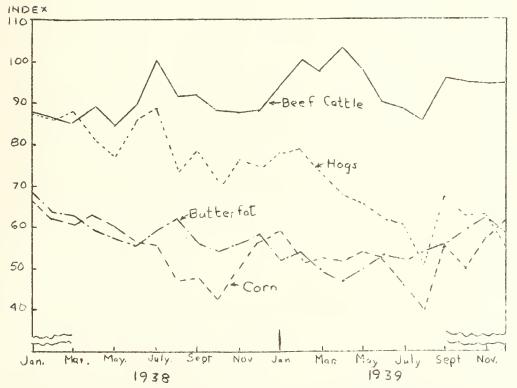

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 5 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: cats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs iropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and cats, 97.

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low cat yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corm, cats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

FARM BUSINESS REPORT . . . 1939

FARMING-TYPE AREA NINE Southern Fruit and Vegetable Area

DEPARTMENT OF AGRICULTURAL ECONOMICS, UNIVERSITY OF ILLINOIS
COLLEGE OF AGRICULTURE, EXTENSION SERVICE IN AGRICULTURE AND HOME ECONOMICS
URBANA, ILLINOIS

Annual Farm Business Report

ON FIFTY-SIX FARMS IN FARMING-TYPE AREA 9, 1939

By P. E. Johnston, J. B. Cunningham, and E. N. Searls

Farm earnings of accounting farms in Farming-Type Area 9 were higher in 1939 than in 1938. The net earnings per acre averaged \$3.31 in 1939, \$2.73 in 1938, and \$3.41 in 1937. The items considered in calculating the net earnings included inventory changes, cash receipts, cash expenses, the value of the farm products used in the household (in 1938 and 1939 only), and unpaid family labor (Table 1).

Farming-Type Area 9 Fruit and Vegetable

Since the value of farm products used in the household was not included in the records prior to 1938, the earnings for 1938 and 1939 are not strictly comparable to those for other years. The value per acre of farm products used was \$1.27 in 1938 and \$1.23 in 1939.

The accounting farms were larger than average, crop yields were above average, and the farms as a whole were operated with efficiency which was greater than average. Therefore, the figures contained in this report represent conditions which are better than average for this area. This fact is borne out by survey records taken in various areas of the state.

High crop yields, accompanied by increased industrial activity and improved demand for farm products especially during the latter half of the year, were the principal factors producing higher earnings in 1939 (Figs. 1, 2, and 3).

General farms, on which considerable grain and livestock was produced, predominated among the accounting farms even tho Farming-Type Area 9 is the Fruit and Vegetable Area of the state (Table 4).

^{1/} R. J. Mutti supervised the closing of the farm accounts and the preparation of the tables used in this report. The farm accounts project was conducted in cooperation with the farm bureaus in the following counties and was supervised by the farm advisers indicated:

W. C. Anderson, Johnson County

J. R. Strubinger, Massac County

E. A. Bierbaum, Union County

J. G. McCall, Jackson-Perry Counties

A. A. Pease, Pulaski-Alexander Counties

G. C. Smith, Pope-Hardin Counties

Inventory Changes, Cash Receipts, Cash Expenses, and Earnings

Inventory changes. -- The year 1939 was the third consecutive year of increasing inventories, the increases averaging \$12 in 1939, \$51 in 1938, and \$325 in 1937 (Table 1). These increases were made despite decreases in value of improvements. The largest increases in 1939 were in feed and grain. The increased value of feed and grain represented higher prices at the end of the year as there were only slight changes in the quantities of grain on hand (Page 1 and Fig. 2). The average amounts of grain on hand in Area 9 at the two inventory periods follow:

	Beginning of year (bushels)	End of year (bushels)
Corn	699	707
Oats	73	51
Wheat	43	56

Cash receipts. -- Cash receipts reached the highest level in three years, averaging \$2,831 in 1939 (Table 1). AAA receipts and sales of feed and grain (including fruit and vegetables) were larger in 1939 than in 1938, but livestock sales were smaller. The larger AAA receipts were mainly due to a doubling-up in payments, many farmers receiving payments in 1939 for participation in both the 1938 and 1939 programs.

Cash expenses. -- Cash expenses were larger in 1939 than in either 1938 or 1937. Less money was spent for productive livestock and machinery in 1939 than in 1938, although more was spent for improvements, feed and grain, and labor.

Earnings. -- Cash receipts exceeded cash expenses in 1939 by \$896, or by a larger margin than for 1938 but by a smaller margin than for 1937. Cash balance, the difference between these receipts and expenses, is the average amount of money available for family living expenses, interest, debt payments, and savings.

The amounts deducted for operator's and family labor remained rather uniform during the 4-year period, a difference of only \$84 occurring between the low year, 1938, and the high year, 1937. The uniformity in valuation was due to the fact that approximately the same amount of family labor was available each year and to the fact that the same rate (\$40 per month) was charged for the physical labor of the operator and other mature members of the family.

The net earnings per farm averaged \$615 in 1939 as compared with \$613 for 1938. The figure representing net earnings per farm is the sum remaining as compensation for the use of the capital invested in the business and for the managerial ability of the operator. It is calculated by adding the value of farm products used in the household and the inventory increases to the cash balance and by subtracting the value of unpaid labor from the resulting total. Therefore, this figure indicates the earning power of the business and determines the real value of the farm and its equipment.

Variation in farm earnings. -- A wide variation was found in earnings on the farms in Area 9; for example, 17 farms earned less than 3 percent on the investment, with an average loss of 5.4 percent, but in contrast 22 farms earned 9 percent or more, with an average rate earned of 12.6 percent. After deducting all farm expenses and a charge of 5 percent for the use of the capital invested in the business, the former group of operators had a loss of \$933 for labor and management earnings as contrasted with a gain of \$1,458 for the latter group. By studying the reasons for these variations, farm operators can improve their chances of financial success. The variation in earnings and in size of farm for all records in the areas was as follows:

				Capital			
Rate	Number	Average	Acres	in-	Gross	Net	Labor and
earned on	of	rate	per	vested	earnings	earnings	management

9 or more	22	12.6	205	13,551	4,123	1,714	1,458

Comparison of Farms According to Percent of Land Area Tillable

The 56 farms were divided into two groups according to the percent of land area tillable. Of this total number of farms, 31 had 85 percent or more of land area tillable, and 25 had less than 85 percent tillable. The average percent tillable was 91.2 for the former group and 68.8 for the latter group.

There was a tendency for the farms with the larger percent of land area tillable to have low-producing gray prairie soil and for the farms with the smaller percent of land area tillable to have rough land associated with small areas of high-producing bottomland.

This grouping of farms gives each farmer an opportunity to compare his farm with the average of other farms having a similar percent of land area tillable as well as with the average of all accounting farms (Tables 2 and 3).

The capital investment averaged \$12,553, or \$74 per acre, for the group of farms having the larger percent of land area tillable, as compared with a capital investment averaging \$10,618, or \$51 per acre, for the group of farms having the smaller percent of land area tillable.

The receipts and net increases averaged \$222 larger and expenses and net decreases \$684 larger on farms having the larger percent of land area tillable than on the farms having the smaller percent of land area tillable. The livestock receipts were \$40 smaller for the farms with the larger percent of land area tillable, whereas the grain receipts were \$379 larger. The rate earned on investment was 3.3 percent and 8.1 percent and the labor and management earnings were \$178 and \$746, respectively, for the two groups of farms.

The farms with the larger percent of land area tillable were 38 acros smaller than were those with the smaller percent of land area tillable; yet the former had 10 acres more land in crops. The amount of livestock per farm was practically the same for both groups of farms, as indicated by the value of feed to productive livestock and the capital invested in productive livestock (Tables 2 and 3).

Since much of the productive bottomland on the accounting farms was associated with untillable land on which the farmsteads were located and since much of the tillable prairie land was relatively unproductive, no apparent relationship existed between the percent of land area tillable and land use or between land area tillable and crop yields.

Larger crop yields, amounting to 4.8 bushels of corn and 1.0 bushel of wheat, were secured on the farms with the smaller percent of land area tillable.

Livestock efficiency, as measured by returns per \$100 worth of feed fed, poultry returns per hen, and returns per litter farrowed, was lower on that group of farms with the larger percent of tillable land than on that group with the smaller percent of tillable land, but the efficiency, as measured in terms of dairy returns per cow, was larger on the former group of farms.

The operating expenses per acre averaged \$12.18 on the farms with the most tillable land and \$6.72 on the farms with the least tillable land. The combined cost per crop acre for labor, machinery, and horses was \$3.54 larger on the farms with the larger percent of tillable land, but the combined cost per acre for improvements and taxes was \$1.01 smaller.

Source of Income

The 56 farms were divided into 4 groups according to source of income (Table 4). The items in this table, for the most part, were made to correspond with the items given in Table 3; therefore, a farmer may compare the data in the "Your farm" column of Table 3 with the "Source of income" column in Table 4, which corresponds to the classification for his own farm.

In a comparison of the groups of farms the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that generally the grain farms were located on the better land: high value of land per acre, large percent of land area tillable, large percent of land in grain, and land tax per acre.

The returns per \$100 feed that are necessary to pay for feed (including pasture) and other costs, according to 5-year averages of complete cost studies (1933-1937), are as follows: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. There is little wonder, therefore, that the 4 groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. The amount of feed fed per acre to productive livestock averaged \$5.42 on the general farms with the most livestock but only \$2.16 on the grain farms.

Differences in expenses are significant for the 4 groups of farms. Labor input was highest on the fruit and truck farms, where 36.7 months of labor were used, and lowest on the grain farms, where 18.5 months of labor were used; horse and machinery cost per crop acre averaged \$6.31 on the fruit and truck farms, \$4.55 on the general farms with the most livestock, \$3.86 on the general farms with the least livestock, and only \$3.17 on the grain farms; improvement costs per acre ranged from \$.35 on the grain farms to \$3.15 on the fruit and truck farms; and land taxes ranged from \$.56 on the fruit and truck farms to \$.96 on the grain farms.

Size of Farm As Related to Earnings

The farm records in Farming-Type Area 9, when sorted according to the total acres in the farm, indicate that the larger farms had a greater total investment in land, improvements, and equipment than did the smaller farms. The operators on the larger farms took in more money during the year than did the operators on the smaller farms; and after deductions were made for farm business expenditures and interest on the investment, the 19 largest farms had labor and management earnings which averaged \$715 as contrasted with \$382 for the 13 smallest farms. The earnings, as measured by the rate earned on the investment, were also higher for the 19 largest farms. In years when the average rate earned on investment for groups of farms exceeds the capitalization rate (5 percent), the average labor and management earnings are higher on the larger farms than on the smaller ones, but these earnings are lower when the rate earned averages less than the capitalization rate.

The smallest farms were operated more intensively than were the largest farms. This variation was indicated by the higher gross earnings per acre, by the larger proportion of total land tillable, by the higher land values, by the larger amount of feed fed per acre to productive livestock, and by more months of labor per 100 crop acres.

The method used to increase the volume of business depended upon the individual farm. Some farm operators apparently increased the volume of their business by improving the quality and increasing the amount of livestock; others, by growing more intensive crops, by increasing crop yields, or by developing special markets; still others, by increasing the acreage operated or by applying combinations of the above methods.

Farm Organization and Farm Earnings by Counties and Groups of Counties

Farming-type areas are formed by grouping together counties which are similar with respect to physical, economic, and biological characteristics. Although a classification of this kind is very useful for many purposes, no two counties within an area are exactly alike. Averages are calculated for each county in the state from which 30 or more records are received. Such tabulations of farm account records by counties and groups of counties indicate some of these differences which are due to variations in quality of land, topography, amount of erosion, market outlets, weather conditions, and disease hazards. The effects of variations in these factors are indicated in the account records by differences in value of land per acre, taxes per acre, percent of land area tillable, size of farm, total acres in crops, percent of tillable land in important crops, crop yields, amount of feed fed to productive livestock, and the source of farm income.

The tabulations by counties and by groups of counties may be used by extension specialists, farm advisers, and county program-building committees to represent the type of farm organization and the level of operating efficiency attained by a selected group of progressive farmers in the various parts of a farming-type area. Since the personnel of the accounting group changes slowly, comparisons may be made from county to county and from year to year even though these records are from farms with efficiency which is higher than average.

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Frograms which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1, 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even though 62 million bushels of 1937 and 1938 corn were placed under scal at the end of the year and 83 million bushels of 1939 corn were scaled by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939; dairy cows, 2 percent; beef cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.7 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were greater at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

<u>Frices of important farm products.</u>—-Frices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these price increases occurred during the last four months of the year.

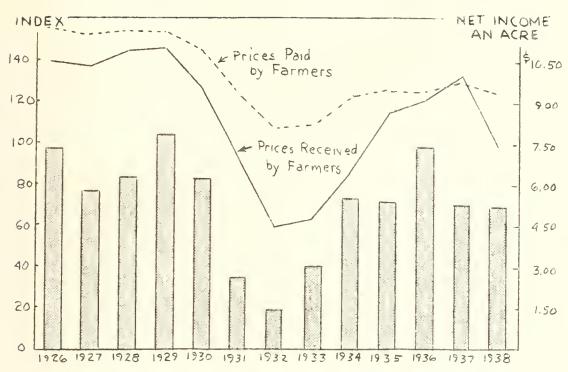

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

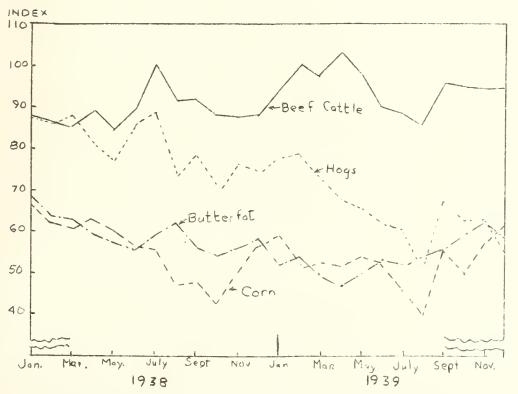

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butteriat, 2 cents per pound; eggs, 5 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1959 as in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and oats, 97.

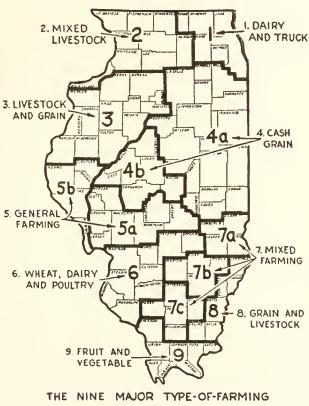

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop-yield indices under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop-yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low out yields. Fifty-five counties, which were well-distributed over the state, had crop-yield indices from 121 to 135.

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corn, oats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

Summary of Annual Farm Business Reports on 2,713 Illinois Farms

For the Year 1939

THE NINE MAJOR TYPE-OF-FARMING AREAS IN ILLINOIS

Department of Agricultural Economics

and Home Economics
University of Illinois, Urbana
June, 1940

OF THE

SUMMARY OF FARM BUSINESS REPORTS

ON

TWO THOUSAND SEVEN HUNDRED THIRTEEN FARMS IN ILLINOIS

FOR 1939

P. E. Johnston, J. B. Cunningham, and M. L. Mosher

The following summary is a record of income, expenditures, and earnings on Illinois accounting farms for 1939 and also a record of comparisons of selected items with similar records for other years. The data contained in this report represent Illinois farm conditions which are better than average because the accounting farms are larger than average, the crop yields are above average, and the farms on the whole are operated with efficiency which is greater than average. Records of this type are useful for showing variations in income from year to year and for demonstrating differences between farming-type areas. The variation in income from farm to farm within the groups is shown in Table 3.

The average net cash income an acre for Illinois accounting farms was practically the same for the years 1934, 1935, 1937, 1938, and 1939 (Fig. 1).

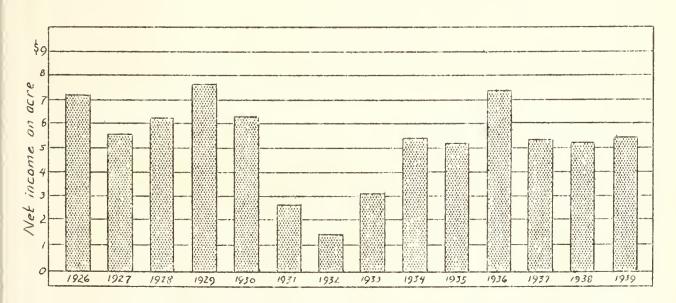

Fig. 1. -- Net cash income an acre (unpaid labor deducted), average for Illinois accounting farms, 1926-1939.

The net cash income an acre was computed by subtracting the value of unpaid labor from the cash balance for the year and then by dividing that difference by the number of acres in the farm. Farming-type-area averages were weighted by the number of acres in the farms in each farming-type area in order to calculate the state averages.

The weighted average net cash income an acre for Illinois accounting farms was as follows:

1926	\$7.30	1931	\$2.69	1936	\$7.40
1927	5.74	1932	1.47	1937	5.33
1928	6.22	1933	3,00	1938	5,25
1929	7.78	1934	5,40	1939	5.40
1930	6.22	1935	5.14		

These returns do not include the inventory changes or the money value of food, fuel, and other items of living, all of which are secured from the farm. Net cash income an acre is one of the best measures for comparing incomes of groups of farms over a period of years or for contrasting the level of income for different type-of-farming areas, because the net cash income is not influenced by changes in the inventory of land. During any period of years, earnings fluctuate more widely from year to year when inventory changes are included. On the inventory basis, earnings are lower in the low-income years and higher in the high-income years, because there are usually inventory losses when prices are declining but inventory increases when prices are rising.

In the farm business reports published in 1938 and 1939 and in the printed tables at the back of this report, the value of farm products used in the household was included as a source of income. In comparing the 1938 and the 1939 records with those for other years, the value of farm products used in the household has been omitted because the data are not available for years prior to 1938. The average value of farm products used in the household was \$272 per farm, or \$1.19 an acre, for all accounting farms in Illinois for 1938 and \$252 per farm, or \$1.09 an acre, for 1939. The averages for the various farming-type areas are as follows:

Value of farm products used in household, 1938 and 1939

	1.1.	i ilousciioiu,	1300 and 1303			
	Per	farm	Per a	acre		
	1938	1939	1938	1939		
Area 1	\$267	\$241	\$1.43	\$1.41		
	••			-		
Area 2	265	250	1.28	1.20		
Area 3	278	260	1.12	1.05		
Area 4	265	251	1.01	.94		
Area 5	279	256	1.15	.9 8		
Area 6	290	264	1.40	1.31		
Area 7	268	254	1.24	1.12		
Area 8	252	239	1.24	1.10		
Area 9	284	229	1.27	1.23		
State average	\$272	\$252	\$1.19	\$1.09		

^{1/} The average is weighted by the acres of land in farms in each farming-type area as reported by the census.

Cash income per farm. -- The average cash income per farm, the cash expenditures per farm, and the cash balance per farm were all larger in 1939 than in 1938 (Table 1). According to farm account records, both cash income per farm and cash expenditures per farm were larger in 1939 than in any other year since 1926. The cash balance was larger in 1939 than in any other year since 1930 with the exception of 1936. When inventory changes are included, the average net farm income was larger in 1939 than in any other year since 1926 with the exception of 1936. A part of the larger income for 1939 was due to an increase in the size of farm--in 1939 the farms averaged 5 acres larger than in 1938 and 38 acres larger than in 1926.

Table 1.—Selected Items of Income and Expense on Accounting Farms in Illinois, 1934-1939

Item	1934	1935	1936	1937	1938	1939
Acres per farm Cash income per farm Cash expenditures per farm Cash balance Inventory increase Cash balance plus inventory increase Unpaid labor Net farm income	1 865 \$1 827 530 \$2 357 670	\$4 342 2 605 \$1 737 779 \$2 516 668	\$5 374 3 034 \$2 340 802 \$3 142 740	3 424 \$1 885 727 \$2 612 733	\$5 285	\$5 920 4 001 \$1 919 1 117 \$3 036 696
Gross receipts per acreb Total expense per acrec Net receipts per acre (cash basis)	\$15.28 7.81 7.47 5.40	8.68 8.46	9.06 10.49		*	10.26

A In this table and in succeeding tables where data are on a farm basis rather than on an acre basis, state averages were obtained by weighting area averages by the number of farms in each area.

Inventory increases. -- The average inventory increase was larger in 1939 than in any other year for which averages have been calculated from farm account records, this increase being $2\frac{1}{2}$ times as large as it was in 1938. There have been inventory increases for each of the last 6 years, and these increases have ranged from \$428 per farm in 1938 to \$1,117 per farm in 1939. An inventory increase means that the combined value of livestock, grain, improvements, and machinery was larger at the end of the year than at the beginning. Therefore, this series of inventory increases for a period of 6 years reflects an increase in the price level and an accumulation of grain and livestock following the drouth of 1934. Enough money has been spent for machinery and improvements so that the value per farm has increased even though deductions have been made for normal

b/ Gross receipts include inventory changes.

c/ Total expense includes unpaid labor.

^{1/} No data for the years prior to 1934 are presented in this report.

depreciation. Earnings are larger during the last 6 years if inventory changes are included than if calculations are made on a cash basis. On the other hand, inventory losses averaged \$866 a year for the 3 years 1930-1932. The cash basis more nearly reflects the ability of the farmer to pay his interest, to buy the things that the family needs, and to add something to the savings than does the method of accounting which includes inventory changes.

Cash farm business expenditures, --Illinois accounting farmers spent more money to run their farms in 1939 than in any other year since 1926. Expenditures averaged 17 percent larger in 1939 than in 1938 (Table 2). More money was spent in 1939 than in 1938 for improvements, feed, labor, taxes, and livestock, but slightly less was spent for machinery and crop expense. The higher expenditures for feed and livestock indicate the rate at which livestock production was expanding on Illinois farms. This expansion was primarily for hogs, feeder cattle and beef-cow herds.

Total cash expenses	\$1	865	\$2	605	\$3	034	\$3	424	\$3	421	\$4	001	117

Cash expenditures for improvements were 17 percent larger in 1939 than in 1938 and were almost 3 times as large in 1939 as in 1934. Expenditures for machinery, although slightly smaller in 1939 than in 1938, were over twice as large in 1939 as in 1934. Taxes were slightly higher in 1939 than in 1938, partly because the farms were larger but also because tax rates advanced, as is indicated by higher tax returns an acre for practically all sections of the state.

Variations in earnings from farm to farm. -- State averages and earnings for the farms included in the area vary widely. Much of the farm-to-farm variation is due to the managerial ability of the operators and to the manner in which the farms are organized and operated. The records were grouped for this study into high-, medium-, and low-income farms on the basis of the rate earned on investment. The value of farm products used in the household was included as a farm receipt in this tabulation. The records for LaSalle, Livingston, McLean, Tazewell, and Woodford counties were omitted from the average for Area 4. The wide variation in rate earned on investment, net receipts per farm, and labor and management earnings indicates the opportunities which some farmers have for improving the income from their farms, because these variations are largely due to factors over which the operator has some control (Table 3).

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms on December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of 3 years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs, which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were found on Illinois farms on January 1, 1940, as compared with 325 million bushels on January 1, 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even though 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2,520 accounting farms in Illinois from the beginning to the end of 1939: dairy cows, 2 percent; beef cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows per farm farrowed on accounting farms in 1939 as contrasted with 9.9 sows per farm in 1938. The increase in beef-cattle numbers is a part of the general upswing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were greater at the time the 1939 closing inventory was taken than at any other inventory period in several years; and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Prices of important farm products.—Prices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these price increases occurred during the last four months of the year.

December 15. Illinois	Farm Prices

Chickens, 1b.	.13	.11	phi call	.02

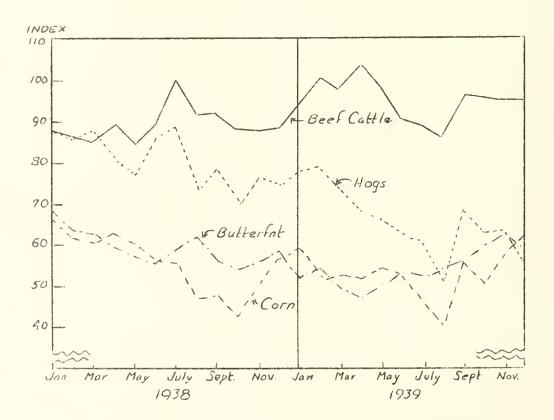

Fig. 2.--Monthly price indices of the average farm prices of corn, hogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 = 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corn, 2 cents a bushel; wheat and soybeans, 1 cent a bushel; hogs, \$1.50 a hundred; butterfat, 2 cents a pound; eggs, 3 cents a dozen; and chickens, 2 cents a pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents a bushel; beef cattle, 50 cents a hundred; lambs, 42 cents a hundred; wool, 4 cents a pound; and apples, 12 cents a bushel (Fig. 2).

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939, as in 1938, livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average; grains, from 74 to 72 percent; chickens and eggs, from 106 to 94 percent; and dairy products, from 106 to 104 percent.

The corn-hog ratio also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average 1929-1938. Corn contributed more than did any other crop to the high average yields. The acre yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and oats. 97.

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop yield indices under 105. In contrast to these counties, 31 had indices over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north-central Illinois. Crop yield indices were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low oat yields. Fifty-five counties, which were well distributed over the state, had crop yield indices from 121 to 135.

Variations in Earnings by Farming-Type Areas

Farm incomes vary widely among different sections of the state. Much of the sectional difference is normal from year to year because the productivity of the soil varies widely in different parts of Illinois. Other important factors are: (1) differences in crop yields due to weather, disease, and insect damage and (2) variations in the relative price levels of major products sold in the different areas.

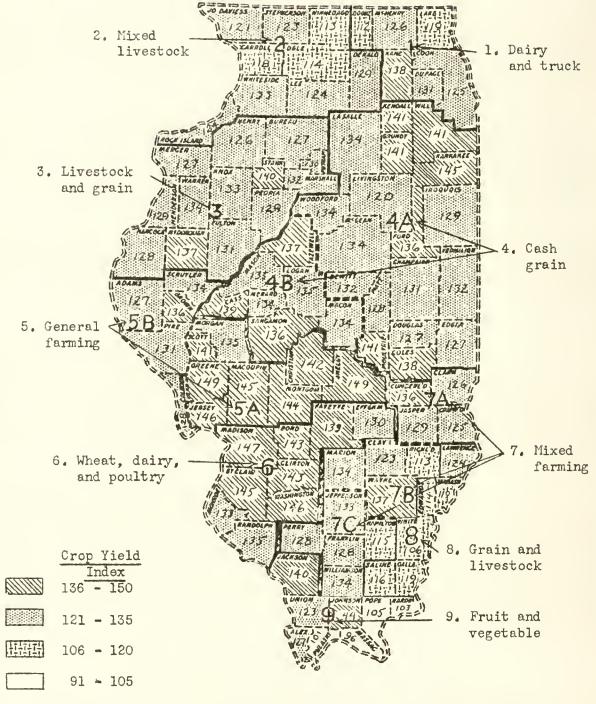

Fig. 2.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indices are based on county yields of corn, oats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

Variations in net cash income an acre. -- The average net cash income an acre for Illinois accounting farms in 1939 varied from \$1.39 in Area 7 to \$7.08 in Area 4 (Table 4). Cash incomes were higher in 1939 than in 1938 for Areas 4, 6, and 8, but they were lower for Areas 1, 2, 3, 5, and 7. Cash incomes were higher in Areas 4, 6, and 8 because grain prices increased and because crop yields were abnormally high in Area 6 and better than average in Area 4. In Area 1, crop yields for 1939 were above the 10-year average; but in several other areas in the state, they were below the 10-year level. This comparative rating accounts for the fact that the Chicago Dairy Area had a lower income in 1939 than in 1938 and for the fact that the St. Louis Dairy and Wheat Area had a higher income in 1939 than in 1938. Cash incomes in the livestock areas were reduced by the sharp decline in hog prices in 1939.

Table 4.--Net Cash Income an Acre for Illinois Accounting Farms by Farming-Type Areas for the Periods 1925-1929 and 1930-1934 and for 1936, 1937, 1938, and 1939

Farming-type areas	1925 - 1929	1930 - 1934	1936	1937	1938	1939
Area 1, Chicago Dairy Area 2, Northwestern Mixed Livestock Area 3, Western Livestock and Grain Area 4, East-Central Cash Grain Area 5, West-Central General Farming Area 6, St. Louis Dairy and Wheat Area 7, South-Central Mixed Farming	7.94 9.05 8.91 6.35 3.26 2.21	4.92 4.86 4.46 3.23 2.03	9.31 9.11 9.88 4.98 3.39 2.73	7.30 6.12 6.26 4.72 3.29 1.28	6.88ª 6.69ª 4.64 2.84 1.41	\$4.04 5.76ª 6.83ª 7.08ª 4.55 3.69 1.39
Area 8, Wabash Valley Grain and Livestock State Average (weighted by acres in area)	4.57	1.73	4.41	4.11	2.63	4.19 \$5.40

A These areas include records from the Farm Bureau Farm Management Service for 1938 and 1939 only: in 1938, 67 records for Area 2, 227 records for Area 3, and 293 records for Area 4; in 1939, 88 records for Area 2, 215 records for Area 3, and 294 records for Area 4. Incomes for Area 4 are slightly higher for the service records than for those from the state-wide extension project.

Inventory changes by farming-type areas. -- There was an average inventory increase of \$1,117 per farm in 1939, and this amount included inventory increases for all major items for all areas except improvements in Area 1 and feed and grain in Area 8 (Table 5). Farmers in Area 1 did not spend enough on improvements in 1939 to offset the depreciation; their cash income an acre was lower in 1939 than in any other year since 1935. Crop yields in Area 8 were above average, but they were lower than those for other sections of the state.

Over half of the average inventory increase was for grains, and this increase reflects the effects of abnormally high crop yields in 1939, higher prices at the end of the year than at the beginning, and the grain sealing program. Sealed grains were carried in the accounts as an inventory rather than as a sale. The increase of \$247 per farm for livestock resulted from a large increase in numbers rather than from an increase in price, because prices for horses, hogs, and chickens were lower at the end of the year than at the beginning.

Table 5 Inventory Incre	ases by Farming-Type Areas, 1	1939
-------------------------	-------------------------------	------

Farming-type areas	Live- stock	Fe an gr	d	Machinery	Improve- ments	Tot	tal
Area 1. Chicago Dairy	\$430	\$	374	\$ 87	\$ -4	\$	887
Area 2. Northwestern Mixed Livestock	483		521	83	104	1	191
Area 3. Western Livestock and Grain	249		960	144	187	1	540
Area 4, East-Central Cash Grain	225	1	163	92	211	1	691

Area 6, St. Louis Dairy and Wheat	142		332	69	54		597
Area 7, South-Central Mixed Farming	121		138	92	56		407
Area 8, Wabash Valley Grain and Livestock	136		-4 3	45	47		185
Weighted Average	\$247	\$	651	\$ 97	\$122	\$1	117

The increase in inventory of \$97 per farm for machinery and \$122 per farm for improvements indicates that farmers are still replacing equipment that should have been replaced during the depression period. The inventory increase for machinery was less in 1939 than in 1938, but the increase for improvements was larger.

On January 1, 1940, the average accounting farm had 3,274 bushels of corn and 537 bushels of oats on hand as contrasted with 2,789 bushels of corn and 640 bushels of oats on hand on January 1, 1939 (Table 6). The amount of corn on the accounting farms increased in all of the areas except Area 8. The decrease in the amount of oats on the accounting farms was confined to the northern two-thirds of the state, because the inventory for Areas 6, 7, and 8 showed an increase, A record carryover of corn is anticipated for October 1940.

Table 6.--Bushels of Corn and Oats in Inventories on Accounting Farms by Farming-Type Areas, January 1, 1939 and 1940

deighted Average	2 789	3 274	640	537

Variations in net income an acre with inventory changes included.—When inventory changes are included, the average net income an acre on Illinois accounting farms was 45 percent higher in 1939 than in 1938; when calculations are made on the cash basis, however, the increase was only 3 percent. The average net

income of \$10.33 an acre was larger in 1939 than in any other year since 1925 with the exception of 1936 (Table 7). Incomes have been larger on the inventory basis than on the cash basis for all years since 1925 with the exception of 1930, 1931, and 1936.

Table 7.--Net Income an Acre (Inventory Basis) for Illinois Accounting Farms by Farming-Type Areas for the Periods 1925-1929 and 1930-1934, and for 1936, 1937, 1938, and 1939

Income From Agricultural Conservation Payments

Cash farm incomes of accounting farmers in 1939 included agricultural conservation payments which were received during the accounting year for participation in both the 1938 and 1939 programs. On many farms both payments were received in 1939; this doubling-up of payments accounts for a high average payment of \$531 per farm for cooperating farms as compared with \$267 for cooperating farms in 1938. Ninety percent of the accounting farmers in Area 6 cooperated in the program in 1939, and the percents in other areas range up to 96 percent, which is the percent for Area 3 (Table 8). The payment an acre ranged from \$.85 in Area 7 to \$3.25 in Area 3, and payments in all areas were much higher than were taxes; they were over twice as high as taxes in Areas 2, 3, 4, 8, and 9.

Source of Income

The 1,837 farms in Areas 2, 3, 4, and 5 were divided into 6 groups according to their source of income (Table 9). Similar tables for other areas can be found in the various area reports which are available.

In a comparison of the groups of farms, the fact that conditions affecting production and price relationships vary from year to year should be kept in mind. Therefore, the average differences in earnings in 1939 are not necessarily typical of the variations that may be expected over a long period of years. The following items, for example, indicate that the grain farms were generally located on the better land: high value of land an acre, large percent of land area tillable, large percent of land in grain, and high taxes an acre.

a For these areas records from the Farm Bureau Farm Management Service are included.

Table 8.--Percent of Illinois Accounting Farmers Receiving Agricultural Conservation Payments in 1939 and the Payments Per Farm and Per Acre, by Farming-Type Areas

Area	Number of farms	Acres per farm	Percent of farms receiving payments	Payments per farm, all farms	Payments per farm, cooperat- ing farms	Payments per acre, cooperat- ing farms	Taxes per acre, all farms
Area l	87	171	91	\$311	\$343	\$2.01	\$1.43
Area 2	454	209	93	576	616	2.95	1.27
Area 3	511	249	96	782	810	3.25	1.29
Area 4	853	267	95	771	810	3.04	1.45
Area 5	315	261	94	454	483	1.85	1.11
Area 6	271	202	90	229	255	1.26	,81
Area 7	103	227	93	179	192	.85	.58
Area 8	63	218	91	338	374	1.72	, 83
Area 9	56	186	95	259	274	1.47	.73

According to the 5-year average (1933-1937) of complete cost studies, the necessary returns per \$100 worth of feed fed are as follows: poultry, \$195; dairy cattle, \$157; hogs, \$127; and feeder cattle, \$117. These returns are necessary to pay for feed (including pasture) and other costs. There is little wonder, therefore, that the 6 groups of accounting farms with different classes and proportions of livestock varied widely in their returns per \$100 worth of feed fed. In 1939, the average return per \$100 worth of feed fed (excluding pasture) was \$198 for dairy farms and \$144 for cattle farms. The amount of feed fed an acre to productive livestock averaged \$15.23 on the cattle farms but only \$4.50 on the grain farms.

Differences in expenses are significant for the 6 groups of farms. Although the total labor input of 28.1 months per farm was largest on the cattle farms and the labor input of 20.9 months per farm was smallest on the grain farms, the labor input of 26.9 months per 100 crop acres was approximately twice as large on the dairy farms as on the cattle farms, where it was 13.6 months. Although the total labor cost per crop acre was lowest (\$5.22) on the grain farms, the labor cost per day of productive work on crops and livestock, as calculated for the Farm Bureau Farm Management Service farms only, was highest (\$3.58) on the grain farms and lowest (\$2.87) on the hog farms.

Horse and machinery costs per crop acre were highest (\$8.05) on the dairy farms and lowest (\$4.41) on the grain farms. However, on Farm Bureau Farm Management Service farms, horse and machinery costs per day of productive work on crops and livestock were lowest (\$2.01) on dairy farms and highest (\$3.21) on grain farms.

Improvement costs an acre ranged from \$.92 on the grain farms to \$1.33 on the dairy farms. Land taxes ranged from \$1.09 on the cattle farms to \$1.21 on the grain farms.

^{1/} The Fifteenth Annual Report of the Farm Bureau Farm Management Service for 1939, AE-1410, has references on the total labor cost.

Table 9. -- Source of Income Related to Farm Earnings and Other Factors for Accounting Farms in Farming Type Areas 2, 3, 4, and 5, 1939

a/ Machinery includes farm share of automobile.

b/ Expenses include operator's and family labor.

c/ Productive work includes Farm Bureau Farm Management Service farms only.

The rate earned on investment was highest on the grain farms and lowest on the hog farms. The general farms (with no single source of income as large as 40 percent of the total) had lower earnings than did the specialized farms, and the general farms with the most livestock had lower earnings than did the general farms with the least livestock. The data for 1939 are very similar to averages for the same areas for the 10-year period, 1926-1935 (Table 9).

Size of Farm

In 1939, the rate earned on investment was the same for the 4 groups containing farms larger than 200 acres, except for the group with 361 to 440 acres. Earnings were smallest for the farms containing from 41 to 120 acres. Labor and management earnings increased from \$853 per farm for the smallest farms to \$3,600 per farm for the largest farms. In years when average earnings are low, the large farms show the largest losses when these losses are measured by labor and management earnings.

The feed fed an acre to productive livestock decreased from \$10.38 on the small farms to \$7.75 on the large farms, and the labor cost per crop acre declined from \$10.00 to \$5.13. The months of labor per 100 crop acres were 20.8 on the small farms and 10.0 on the large ones. The 100-acre farms were man-and-a-half farms; the 320-acre farms were 2-man farms; and the 580-acre farms were 3-man farms. The horse and machinery cost per crop acre declined from \$5.60 on the small farms to \$4.48 on the large farms. The saving in machinery and power is much smaller than is the saving in labor because machinery is used on the large farms to replace labor.

Financial Statement and Selected Factors by Farming-Type Areas

Variations in investments, cash receipts, cash expenses, inventory changes, and other efficiency factors are shown by farming-type areas in Tables 11 and 12. These data indicate a wide range of farming conditions in Illinois and afford ample evidence for the need for grouping by farming-type areas.

The accounting farms ranged in size from 171 acres in Area 1 to 267 acres in Area 4, and the average investment per farm ranged from \$11,689 in Area 9 to \$44,371 in Area 4. The average value of land an acre was \$28 in Area 9 and \$116 in Area 4.

The relative proportions of the farm cash receipts that come from the sale of grain, hogs, cattle, dairy products, and poultry in the different areas indicate the reason for dividing the state into 9 type-of-farming areas as outlined on the map on the front cover.

The yields of crops vary from area to area with the productivity of the soil and weather conditions. The highest corn and oat yields were in Area 2, and the lowest were in Area 9. The map on page 9 gives a comparison of 1939 yields with the normal yields for each county.

Expenses per crop acre for labor and for horses and machinery vary with the size of farm, the amount and kind of livestock, the wages for labor, and the

a/ Cash expense includes estimated value of unpaid labor.

type of equipment. The combined expense per crop acre for labor, horses, and machinery was lowest in Area 8, where the farms are fairly large, where the wages are low, and where there is but little livestock, and this combined expense was highest in Area 1, where the farms are smaller, where the wages are higher, and where the feed fed an acre is the largest and is mostly fed to dairy cattle.

Data for Counties and Groups of Counties

Averages were calculated for each county having 30 or more records and for groups of counties having less than 30 records (Table 13). The county averages are arranged according to farming-type areas with the averages for Area 1 at the front of the list and those for Area 9 at the end.

COMPLETE COSTS AND FARM BUSINESS ANALYSIS ON 29 FARMS IN CHAMPAIGN AND PIATT COUNTIES, 1939

By

R. H. Wilcox, K. E. Kinsinger, and H. C. M. Case

INTRODUCTION

This report carries the results of the twenty-seventh year of a continuous farm cost study which began in Illinois in 1913. This study of farm costs was undertaken with the general object of discovering ways and means of securing greater economy in the production of farm products and of helping farmers to improve the organization of their farms through wiser choices of farm enterprises or through improved methods and practices in handling their enterprises.

The Area Studied in 1939

The cost study has been located in Champaign and Piatt counties since 1920. These counties lie in the east-central section of the state close to the Illinois-Indiana line. They are in the center of the cash-grain area of the state. The land is practically all tillable, and the soil is high in natural fertility. The results shown in this report are for 1939, with summary comparisons for 1937 and 1938. The results represent a group of farms in Champaign and Piatt counties only and are not typical of the state as a whole.

Farms in the Study

The farms included in this cost study are about 80 acres larger than are the average-sized farms in the area. The farmers who furnished cost figures secure somewhat higher yields and have better managed farms than do the average farmers in the two counties. These better-than-average farmers probably have somewhat lower costs than do many of their neighbors. On the average, these cooperators are somewhat more efficient as farmers than are others in the same localities. However, this fact offers no particular hindrance to the use of the data for measuring the importance of individual items of cost and their variation from year to year and farm to farm.

The Year 1939

Weather conditions in the early months of 1939 were favorable for winter wheat. In the early spring, however, rains and cool weather retarded field work and crop growth to some extent. Generally favorable growing weather prevailed during the summer and resulted in a rapid growth of most crops. Corn and soybeans produced excellent yields. The corn crop was one of the best on record. Unfavorable weather for oats at filling time resulted in the lowest oat yield since the poor crop year of 1934.

Table 1. -- Distribution of Land in Cost Accounting Farms

Use of land	Acres p 1938	er farm 1939
Harvested crops Rotation pasture Soil-conserving crops (not harvested) Bluegrass pasture Farmstead Idle land	216.9 15.8 13.6 11.9 6.5	204.1 23.7 20.7 10.0 6.4
Total acres in farm	265.3	265.6

There were about 12 less acres of harvested crops per farm in 1939 than in 1938. The acreage of both rotation pasture and soil-conserving crops (not harvested) increased markedly in 1939. Of course, the acreage in soil-conserving crops (not harvested) does not include all of the land that comes under the classification of soil-conserving crops on these farms. Some soil-conserving crops were also in rotation pasture, and a small acreage was among the harvested crops.

Table 2.--Distribution of Crop Area, Average Crop Yields, and Crop Costs on Cost Farms in Champaign and Piatt Counties

	Perce crop		yield ad	rage l per cre	Averag cost bushel	per	Variat: cost per or ton	bushel
Crop	1938	1939	1938	1939	1938	1939	High	Low
Corn Oats (combined) Oats (threshed) Soybeans (combined) Winter wheat (combined) Winter wheat (threshed) Alfalfa hay Clover hay Soybean hay Other crops Soil-conserving crops (not harvested)	39.09 9.35 3.60 27.35 6.27 1.69 2.21 3.06 .94 .84	38.11 5.82 4.96 27.76 5.67 	61.2 34.8 40.5 32.6 27.0 2.8 .9 1.7	62.5 25.2 38.3 31.8 26.8 2.8 1.0 2.2	\$.28 .34 .30 .46 .53 6.72 13.12 11.62	\$.29 .49 .36 .48 .51 6.96 12.63 10.21	\$.44 .75 1.34 .57 1.55 14.74 18.65 20.15	\$.21 .29 .28 .37 .38 3.75 8.82 6.33

The bushel costs of most grain crops were higher in 1939 than in 1938. The winter-wheat cost was an exception to the higher level of 1939 costs. The unit costs of the hays varied as the yields varied.

With the exception of soybeans for grain, the unit costs of every crop grown under the same climatic conditions and under comparable soil conditions on these Champaign and Piatt county farms were twice as much on some farms as on others (Table 2). The unit costs always vary from one farm to another, even in the

same area, largely because of differences in acre yields and in the amount of labor, power, and other expenses used in growing an acre.

CROP PRODUCTION COSTS

Corn

The year 1939 was the third consecutive year of unusually good corn yields. The yield of corn on the cost accounting farms in 1939 was 20 bushels above the 5-year average yield of 1932-1936 for farms in the accounting work. The net cost of producing an acre of corn in 1939 was \$17.89 as compared with \$16.24 in the earlier five years; but in 1939 the acre yield of 62.5 bushels resulted in an average bushel cost of 28.6 cents as compared with an average bushel cost of 38.7 cents for the years from 1932 through 1936.

The cost of growing corn up to the time of harvest was \$7.15. This amount represents the highest growing cost an acre since 1931, with the exception of 1936, when it was \$7.17 an acre. The harvesting cost was also slightly higher in 1939 than in any other year since 1929, with the exception of 1935. The net cost of producing a bushel of corn was about a cent higher in 1939 than in 1938. In 1939, 87 percent of the corn acreage was harvested with mechanical pickers.

Oats (combined)

The oat crop was combined on 55 percent of the oatland in 1939. This percentage was lower than that combined in 1938 and about double that combined in 1936 and 1937. The total cost of harvesting an acre of oats with the combine in 1939 was \$1.90 (Table 4) as compared with \$3.49 which was the binding and threshing cost an acre for the oats threshed (Table 5); but the yield of threshed oats was 13.1 bushels above the yield of combined oats. When oats were combined, the value of the straw saved for use by livestock was \$.05 an acre; but when oats were threshed, the value was \$.94 an acre.

Oats (threshed)

The cat crop was cut with the binder and threshed on 45 percent of the catland in 1939. Threshed cats consistently gave higher yields an acre than did combined cats. One reason for this difference in yield is that the farmers in the cost work tend to combine the catland that has the poorest stand and promises the lightest crop. There was also a relationship between the amount of livestock on these farms and the proportion of the cat acreage cut with the binder and threshed. The cost of producing an acre of cats harvested with the binder and threshed has been consistently higher than the cost of producing an acre of cats harvested with the combine. The yield of the threshed cats, however, has been consistently so much higher than the yield of the combined cats that the bushel cost of cats threshed has been lower than the bushel cost of cats combined.

Soybeans (combined)

On the farms in the study, all the soybean acreage sown for grain beans was harvested with the combine. In only one year (1938) since soybeans were grown for grain in east-central Illinois was the acre yield of the crop as high as it

4.

was in 1939. The average acre yield of soybeans was 31.8 bushels in 1939 as commared with 32.6 bushels in 1938 and 25.6 bushels in 1937. Soybean yields on individual farms in 1939 varied from a low of 23.7 bushels an acre to a high of 37.8 bushels an acre. Bushel costs varied from 37 cents on the farm with the lowest cost to 57 cents on the farm with the highest cost. The average cost of producing soybeans was 48 cents a bushel, or two cents above the lowest cost year (1938).

Winter Wheat (combined)

Sixteen of the 29 farmers who cooperated in this study included winter wheat in their cropping system. The acreage of wheat grown on the 16 farms in 1939 was the smallest since 1933. In the area studied, the crop was characterized by wide differences in yields an acre from farm to farm. In 1939, the acre-yield of wheat varied from 39.3 bushels an acre on the farm with the highest yield to 9.8 bushels an acre on the farm with the lowest yield. Since 1934, the acre cost of producing wheat has ranged between \$14.00 and \$15.00.

Alfalfa Hay

Alfalfa hay was grown on only 18 of the 29 cost accounting farms. The acreage of alfalfa hay per farm varied from 19.79 acres on the farm with the highest alfalfa acreage to 1.67 acres on the farm with the smallest alfalfa acreage. The average alfalfa hay yield an acre was 2.82 tons in 1939 and 2.76 tons in 1938 as compared with 1.96 tons, the 5-year average yield for 1933-1937. The good hay yield of 1939 resulted in a sharp drop in hay prices in the area as soon as farmers started cutting the 1939 crop. Alfalfa was the only important hay crop grown at a profit in the area in 1939.

The net acre cost of the alfalfa crop in 1939 was \$19.61, including taxes and interest on land values and after deducting a small credit for pasture and seed. This amount was about \$1.00 an acre above the 1938 acre cost and over \$2.00 above the 1937 acre cost. However, the cost per ton of alfalfa was about \$2.50 a ton lower in 1939 than in 1937. The pickup baler was used in the field to bale 32.2 percent of the alfalfa hay produced on the farms in the study. When the baler was used, the cost of baling was added to the cost of the crop, and tho hay was credited at baled hay prices.

Clover Hay

Clover hay was grown on only 8 of the 29 farms in 1939 as compared with 10 farms in 1938 and 3 farms in 1937. Increased hay yields in 1938 and 1939 resulted in an average price of \$6.00 a ton for loose clover hay at the time of cutting. Clover hay which was baled in the field was valued at the loose clover hay price plus the cost of baling. The pickup baler was used in the field to bale 64.6 percent of the clover hay produced on the farms in the study. This high percentage of baled hay put the average value of all hay taken from the fields, loose and baled together, at \$7.46 a ton and the average cost at \$12.63 a ton.

Soybean Hay

Only 5 farmers cut more than two or three mower widths around their soybean grain fields and used these cuttings for hay. The average price of soybean hay in the fall of 1939 was \$5.00 a ton. Some credit, however, should be allowed for the fact that cutting borders of soybean fields is as much a method of opening up grain fields for the combine as it is a method of producing hay.

CORN (HUSKED IN FIELD)

LIVESTOCK PRODUCTION COSTS

Hoge

The total amount of pork produced on the cash-grain farms included in this study has been gradually increasing during the twenty years that this cost work has been conducted in Champaign and Piatt counties. The total of 14,649 pounds produced per farm in 1939 was the highest average production of the twenty years, 1920-1939.

The amount of pork produced varied greatly from farm to farm. Of the 29 farms, one produced no pork, 6 produced less than 5,000 pounds, and 8 produced more than 20,000 pounds.

The spring of 1939 was cold and damp, and the litters weamed were smaller than normal. But, because of low corn prices during the growing and feeding seasons, hogs were produced at only slightly higher costs in 1939 than in 1938. The cost figures in Table 12 are for the pork produced by feeding outside cattle lots; it is the hundredweight cost of the 14,175 pounds of pork produced per farm.

When hogs were not following cattle, 390 pounds of corn, or its equivalent in other grains, and 20 pounds of tankage, or its equivalent in protein feeds, were required to produce 100 pounds of pork. All the farmers provided pasture for their hogs although not all of it was legume or mixed-legume pasture. Neither could all of the pastures be classified as clean, since some of them had carried hogs the previous year.

Milk Cattle

Milk cattle are kept on most farms in this area of the state simply to supply the farm family with milk, cream, and butter. On two of the farms, a cow or two in the beef herd was milked. However, these beef herds are not included in Table 13.

The average cost of feed and other items used in caring for an animal unit of dairy stock was \$97.05 in 1939, or \$13.36 more than it was in 1938. Materially more grain and hay were fed to mike cows in 1939 than in 1938; but the milk production per cow was less in 1939 than in 1938. One reason for the increased quantity of feed per animal unit in 1939 was that more of the animals in the herd were mature and were fed for milk production in 1939 than in 1938.

There were 9 farms on which 5 or more dairy cows were kept, but the number exceeded 10 on only 3 of them. For all but one of the herds with more than five cows, the milk yield ranged between 5,000 and 8,000 pounds per cow. In the complete study all of the milk cows that produced only 5,000 to 6,000 pounds of milk had costs of \$1.84 a hundred pounds, but those cows that produced 7,000 to 8,000 pounds of milk had costs of only \$1.37 a hundred pounds. The 13 farms with net profits averaged 7,420 pounds of milk per cow, but the 14 farms with net losses averaged only 5,634 pounds. Even when milk cows are carried as a sideline, the dairy enterprise merits enough attention for a reasonable degree of efficiency.

Feeder Cattle

Nine of the farmers fed calves or yearling steers which were sold during 1939. This total is the largest number of cooperating farmers to feed steers in any year throughout the twenty years that the study has been in progress.

The figures shown in Table 14 are the cost of producing beef from the time the steers were purchased in 1938 until they were sold during 1939. The weight of the steers when they were purchased ranged from 360 to 620 pounds, and the cost of the steers at the farm ranged from \$8.11 to \$9.64 a hundred pounds. The gains which the cattle made while they were on feed ranged from \$7.54 to \$10.20 a hundred pounds and averaged \$8.55.

Feed was 83 percent of the fattening costs. For each 100 pounds of beef gained, the cattle were fed 734 pounds of corn and 200 pounds of hay and were pastured for 13 days. When these steers were sold, their owners received 65 cents a bushel for all the corn fed to them after the market prices for all other feeds had been paid and after all other expenses had been met.

Hogs were placed in the feedlot with all the feeder cattle under study. The gains made by hogs while they were following cattle were credited to the cattle at the average yearly price received for hogs sold from the farm. The gain in weight of the hogs which were running behind cattle depended largely on the age of the steers and the kind and amount of corn fed them. The following factors were used in calculating the gains in hogs when they ran behind feeder cattle:

Pork Per Bushel of Corn Fed Steers (Steers not fed silage)

Kind of corn fed cattle	Yearling steers	Calves
	(lb. of pork)	(lb. of pork)
Broken ear	1.5	en us
Corn-and cob-meal	•5	.3
Crushed ear	.75	.5
Ground shelled	•5	.3
Shelled	1.2	.75
		1

Beef Herds

The number of farms on which beef cows are maintained is not large; but the number is gradually increasing under the soil conservation program. The farmers who used their beef herds as a means of converting farm roughages into meat found beef herds a profitable enterprise in 1939. There was only one beef herd that did not obtain more than 60 percent of its feed during the year from roughages. This herd was composed of only a few beef cows and all of them were milked to supply the household with milk.

It is extremely difficult to place a farm price on the miscellaneous farm roughages and pastures used by beef cows; so, in order to give a check on what returns the cows made on the feed fed them, a figure called "returns to roughage and labor per animal unit" was calculated. This figure shows how much an animal unit of boef cattle returned to its owner during the year for the roughage fed to it and for the labor expended on it after the market prices for all other feeds had been paid and after all other expenses but roughage and labor had been met.

All the beef herds returned something to their owners for roughage and labor, and all but one, a very small herd, paid very well for what might have been surplus roughage and idle labor.

Poultry

The difference between good and poor flock management is clearly shown by the range in net profits realized from poultry flocks. Even when the flock is distinctly a sideline, as it is on most of these farms, good care shows an increase farm income. On all but 3 or 4 of these farms, the flock of chickens was too small to give an economical production of eggs.

Only 7 of the 26 flocks used in the average showed profits, the highest profit being \$198.85. For several years, the size of the "increase," which is shown in Table 16 and which includes chickens sold and increases in inventory, has closely approximated and sometimes has been greater than the income from eggs sold. Because of the two sources of income--poultry and eggs--the net cost per dozen eggs has been calculated by dividing the total cost for the flock between poultry and eggs in the same proportion as the income from these sources. When the cost is figured in this manner, the net cost per dozen eggs in 1939 was 19 cents, the same cost as in 1938.

Sheep

Farm flocks were maintained on 6 of the 29 cooperating farms. One flock was composed of purebred stock, and its income was secured mainly from showings at county and state fairs and from sales of breeding stock. This one flock was the only one that showed a profit in 1939.

A large portion of the feed wthat was consumed by farm flocks on the other 5 farms was nonmarketable. In finding the cost of carrying these farm flocks, an attempt was made to place a market value on most of the feeds that these flocks consumed. This task is a difficult one, and a farmer is never sure that the nonmarketable feed would have brought anything on the market. However, when the market prices were placed on feed and on the labor which was used in carrying the farm flocks, the farm flocks showed no profit in 1939. However, sheep may have returned enough for the nonmarketable feeds and have helped enough in keeping down weeds on the farm to make their handling worth while. Also, in some cases, flocks are being built up by crossing with purebred males; but the inventory value of the breeding flock has not been increased, although the individuals in the flock are really more valuable.

LABOR AND POWER COSTS

Man Labor Costs

The hourly cost of hired help varied from 28 cents on the farm with the highest cost to 20 cents on the farm with the lowest cost. The average hourly cost of hired-man labor on the farms in the study was 24.2 cents. This amount was about one-half cent above the 1938 hourly cost and one cent above the 1937 hourly cost.

For the 29 farms, man labor costs in 1939 equalled 19.5 percent of the total farm expenses. This relationship varied from 8.4 percent to 38.3 percent on the various farms.

a/ Custom labor was the labor coming to the farm with the machinery which was hired to do special farm jobs, such as combining, mechanical corn husking, etc.

Horse Labor Costs

Horse labor costs in 1939 averaged 16.0 cents an hour as compared with 14.6 cents in 1938 and 16.4 cents in 1937. There was an average of only 2.9 work horses per farm; this amount was the smallest number of work horses on cooperating farms in the 20 years of the cost work in this area. The number of hours worked per horse dropped to 433 in 1939 as compared with 446 in 1938 and 818 in 1932.

Horses are fed and cared for according to the number of hours of work they do. In 1939, when a horse was worked 433 hours, the horse was fed only 1,733 pounds of grain and 1,828 pounds of hay; whereas, in 1932, when a horse was worked 818 hours, the horse was fed 3,426 pounds of grain and 2,075 pounds of hay.

Tractor Costs

All but one of the 29 farms used tractors. The tractors used have been classified into four groups for the purpose of cost analysis. Two groups contain two-bottom tractors, and these tractors are separated into one group of only general-purpose tractors and a second group in which all two-bottom tractors are thrown together (Table 19). The two other groups are three-bottom tractors, and these tractors are separated into one group of general-purpose tractors and a second group of standard tractors (Table 20).

Two-plow tractors were used on 22 of the farms, with 4 farms using 2 two-plow tractors. There were only 2 standard two-plow tractors in the group. Two-plow general-purpose tractors were operated an average of 539 hours at an average cost of 49.6 cents an hour in 1939 as compared with 45.1 cents an hour in 1938. The hourly cost of operating a two-plow general-purpose tractor varied from 37.1 cents on the farm where the tractor was operated 970.5 hours to 72.5 cents where the hourly cost was the highest and where the tractor was operated only 426.5 hours. Eighteen of the 28 two-plow tractors had rubber tires.

Three-plow tractors were used on 13 of the 29 farms. Seven of the three-plow tractors were of the general-purpose type. These tractors were operated an average of 669 hours at an average hourly cost of 55.2 conts. All of the three-plow general-purpose tractors were equipped with rubber tires. Seven of the three-plow tractors were of the standard type. One was purchased late in the year and operated only 46 hours; so it is not included in the averages of Table 22. The remaining tractors were operated an average of 435.4 hours at an average hourly cost of 74 cents. Only one of the 7 standard tractors was equipped with rubber tires.

THE ANALYSIS OF THE FARM BUSINESS

The costs, incomes, profits and losses, yields, labor and power requirements, other physical factors in crop production, and the feed and labor used for each livestock enterprise of the 29 farms in the study have been set forth in the preceding pages. The following tables (Tables 23, 24, and 25) bring together in convenient form some pertinent information dealing largely with the farms as a whole. The comparisons afforded here should be of particular value to the individual cooperator in his efforts to improve the management of the farm.

In Tables 23, 24, and 25, the farms are arranged in order of the rate carned on investment. The figures in the other columns do not run in any particular order as far as the size of the figures are concerned. Farms differ in many respects; so usually a farm with a high income has some points of weakness, and a farm with a low income has some points of strength.

At the foot of each column figures are shown for the high- and low-income farms and for the average of the group. These figures are an aid in making comparisons with individual farms.

Description of Table 23 (Page 54)

Rate earned on capital in percent represents the net income of the farm, expressed as a percentage of the total investment. The value of the labor of the farmer and his family is deducted as an expense, but no compensation is allowed for his management.

Total investment per acre gives the combined value of land, improvements (except operator's dwelling), machinery, feed, grain, and livestock, as shown in the opening inventory, divided by the total farm acreage.

Operating capital per acre is the sum of the capital invested in the farm business other than real estate. The principal items in the operating capital are the investment in livestock, machinery, grain, and feed at the beginning of the year. A high operating capital usually indicates an intensive farm business.

Investment and expense under farm buildings per acre shows the total building investment and annual expense reduced to an acre basis. High figures often show overinvestment in buildings, and very low figures often indicate inadequate equipment.

Investment and expense under fencing per acre may represent a considerable burden.

Gross income per acre is the sum of sales, increases in inventory, products used in the household, and perquisites furnished to labor divided by the total farm acreage. The total expense includes cash expenditures, decreases in inventory, perquisites furnished labor, and the value of unpaid labor of farm operator and family.

Net income per acre is the difference between the gross income and the total expense an acre.

Description of Table 24 (Page 56)

Crop acres in farm indicates the acreage upon which work was performed, such as preparing a seedbed, planting, or harvesting.

Investment and expense under crop machinery per crop acre is the burden each acre of crops must bear for the machinery (not including power) which is necessary to work it. The proper balance between modern equipment and low cost is an ever-present problem on most farms.

Man labor cost per crop acre shows the value of hired labor plus the value of the time of the farm operator and members of the farm family. This time is charged at hired man's wages, and is distributed over each crop acre in the farm.

Power cost per crop acre includes the acre cost of horse labor, tractor: power, truck expense, and the farm share of automobile expense. It is one of the larger farm expenses.

Power and machinery cost por crop acre is the total of the power cost and machinery expense shown per crop acro.

Labor, powor, and machinery cost per crop acre shows the combined cost of these three items.

Man labor under cost per \$100 gross income represents the proportion of the income required to pay the total labor bill (operator, family, hired labor, and perquisites).

Power and machinery under cost per \$100 gross income shows the relationship of the machinery plus horse cost to the total income of the farm.

Total farm under costs per \$100 gross income shows the proportion of all income required to pay total expenses.

Crop acres per man is a general measure of labor efficiency. This measure is affected by the amount of livestock and large-scale machinery on the farm.

Labor and power costs per hour appear small when taken by themselves, but they are significant because of the large number of units required in operating the farm.

Description of Table 25 (Page 58)

Labor and management wage indicates the income left to pay for the labor and management of the operator after all the other expenditures and the interest at 5 percent on the total farm investment have been deducted from gross income.

Hours of man labor performed per farm gives the time devoted to the farm business by the operator and hired labor. The figure for operator's labor is growing smaller each year.

Man equivalent per farm represents the average number of men used on the farm and assumes that each man worked 1 847 hours per year, the average number of hours for the 29 operators.

Percent hired labor is of total labor cost indicates the extent to which the farm is dependent on outside labor.

General farm expense includes miscellaneous expenditures of the farm such as taxes on land in the farmstead, farm share of auto expense, farm bureau dues, farm papers, and the other expenditures which cannot be allocated directly to the productive farm enterprises. It also includes labor for the time spent cutting hedgerows, cutting weeds in fence rows, etc. These general or overhead items are grouped together and proportioned to the crop and livestock enterprises on the basis of amounts of man labor used. The cost of these general farm expenses for each hour of labor used on the farm shows the basis of distributing this item.

Investment per acre in productive livestock includes the beginning inventory of livestock other than herses reduced to an acre basis.

Livestock income per acre and returns per \$100 invested in productive livestock vary with the kind of livestock; dairy cattle, hogs, and poultry usually show a more rapid turnover and higher relative returns than do beef herds and sheep.

Returns per \$100 feed fed is a good measure of livestock efficiency, although it obviously is affected by the relative prices of livestock and feed. To be profitable, livestock should pay more than market prices for feed, although some feeds used have little or no sales value.

Feed fed per acre to productive livestock shows the intensity of livestock production on a farm.

Farm Efficiency Chart (Page 61)

Of the 52 comparisons shown in Tables 23, 24, and 25, seventeen have been selected as a basis for a farm efficiency chart.

When the position of each farm in these 17 factors is indicated on this chart, it shows the farm operator in a graphic way some of the more important factors of analysis of his farm business.

FARM EFFICIENCY CHART

Purpose and Organization of the Farm Bureau Farm Management Service

The Farm Bureau Farm Management Service was first organized in Illinois in 1925. The service has proved helpful to cooperating farmers in four ways. First, it enables each one to learn how profitably he has operated his farm as compared with the operation of other farms of the same type. Second, through an annual report it points out clearly those parts of the business that tend to make the farm income high or low. Third, it gives each one the opportunity to learn from the most successful farmers the practices that have led to their success. Fourth, it provides a carefully audited annual record of the farm business that proves helpful in making income tex returns, securing bank credit, adjusting the shares of the tenant and landlord's income, settling estates, and adjusting taxes.

Advisory committees, composed of one representative from each farm bureau and the head of the Department of Agricultural Economics, plan and direct the work. These committees employ fieldmen from among those recommended by the University. They also hold and expend the funds collected from the cooperators.

The fieldmen make five regular contacts with all cooperators during the year. On these visits they assist the men with their records, study the annual report with each cooperator, discuss management problems, and give extra time to those who wish special service in reorganizing some parts of their farm business.

The organization and continuation of the project have been made possible by the hearty support of the farm advisers and their assistants. During the past year the fieldmen, farm advisers, and committeemen were as follows:

FIFTEENTH ANNUAL REPORT OF THE FARM BUREAU FARM MANAGEMENT SERVICE FOR THE YEAR 19391/

M. L. Mosher, W. A. Herrington, E. G. Fruin, B. E. King, H. C. M. Case2/

Average earnings of farms in the Farm Bureau Farm Management Service were higher in 1939 than in 1938 by about \$1600 a farm. About one-half of the increase was due to higher yields and increased inventory values of grain carried over and about one-half to larger AAA payments. These increases in AAA payments which were received in 1939 largely resulted from payments which were received on most farms for both 1938 and 1939 during the year 1939. Earnings realized in cash were about the same in 1939 as in 1938.

Two hundred and seventy-one tenant farm operators, keeping records in this project on farms of higher valued land, received average earnings of \$2473 for their labor and management. Those on the lower valued farms received an average of \$1706 per farm. (Table 1, page 2.) This average includes about \$280 for the sale value of farm produce used in the home, but it does not include the value of house rent, which would have cost about \$240 per tenant family at town and city rates. The landlords on the same farms received average net incomes of 6.12 and 5.03 percent on their capital investments on the farms of higher valued and lower valued land respectively.

Earnings shown in this report are much higher than are those for typical farms of the area. Repeated studies have shown that the average earnings of all farms in an area are much lower than they are for farms included in the Farm Bureau Farm Management Service.

As usual, wide differences in earnings were in evidence between farms having about the same opportunities. The net returns for capital and management averaged \$6291 on the 109 most profitable farms on the higher valued land and \$2902 on the 109 least profitable farms. The two groups of farms were about the same size, were on about the same quality of land, and fed about the same amounts of feed to livestock. This difference of \$3389 a farm was largely due to better yields, better handled livestock, and lower expenses. (Table 2, page 3.)

More hogs and poultry were found on the 109 most profitable farms than on the 109 least profitable farms, as is evidenced by larger investments and much larger receipts. Expenses for farm improvements, machinery and equipment, and labor were from 20 to 25 percent greater on the least profitable farms than on

^{1/} Records of 615 farms were included. Thirty other records were kept but not used in the report because they were not typical farms, having an unusual size or source of income.

^{2/} As head of the Department of Agricultural Economics, H. C. M. Case gives general supervision to the project. The project is under the direct supervision of M. L. Mosher.

the most profitable ones, even though the farms were about the same average size and even though the least profitable farms fed a little less feed to livestock.

The value of farm produce used in the farm home was about 11 percent greater on the 109 most profitable farms than on the 109 least profitable ones. The farm operators of the 109 least profitable farms spent about one-half month less time per man on the farms than did the operators of the 109 most profitable farms.

a/ The cash balance as used in this	report wou	ld be a +	mue aach l	onlande it	ווס י

a/ The cash balance as used in this report would be a true cash balance if all sales and purchases had been for cash. It is really the difference between sales and purchases.

Cash receipts were \$1637 larger per farm on the 109 most profitable farms than on the 109 least profitable farms on the higher valued land. Also, cash expenses were \$205 higher per farm, thus leaving \$1432 more cash balance on the more profitable group of farms (Table 1, page 2).

Likewise, inventory increases were \$1954 larger per farm on the 109 most profitable farms than on the 109 least profitable ones. The inventory increases accounted for about 60 percent of the larger incomes, which average \$3389 larger per farm. Most of this difference occurred in the feed and grain account, where the inventory increase was \$1454 larger for the most profitable group.

a/ The seven efficiency factors used were: (1) crop system rating; (2) feed per acre to productive livestock; (3) crop yield index; (4) all livestock efficiency index; (5) price index; (6) labor accomplishment index; (7) horse and machinery accomplishment index.

Net farm earnings were much higher for farms on which work of aboveaverage quality was done in six or seven of the factors named above than for farms on which above-average work was done in only one or two factors or in none at all.

The nine farms that were above the average of all farms in each of the seven factors earned an average of \$6528 when earnings were adjusted to the average-sized farm. The twelve farms that were below the average in each of the seven factors had an average income of only \$2307. This difference amounts to \$4221 when applied to the average-sized farm. The value of well-balanced farming in which all important parts of the business are done at least fairly well is shown clearly from these data.

b/ The net farm earnings of each group of farms are adjusted to the average capital of all 615 farms considered in this report by applying the rate earned by the group to the average capital of \$49,086.

a/ The limestone and rock phosphate are included with the farm improvements. The investments and expenses per acre of farm buildings and fences is the difference between the investments and expenses per acre of farm improvements and of limestone and phosphate.

Organization of the farm business. The size of farm had little to do with the rate earned on the investment, as the average size of the 109 most profitable farms was approximately the same as the size of the 109 least profitable farms and as there were about as many of the most profitable farms as of the least profitable ones in each size-of-farm group (Table 4 and Chart, page 10).

About the same amount of livestock was kept on the 109 most profitable and the 109 least profitable farms, as is shown by the value of feed fed per acre, \$12.48 and \$12.02 on the respective groups of farms (Table 3, page 4). Moreover, high- and low-earning farms were found in approximately equal numbers in all types of farms (Chart, page 11).

Farm expenses. The individual farmer may well study his expenses per acre as shown in Table 4 to learn whether his expenses are unduly high in one or more items. However, in studying expenses, especially for machinery and labor, he may wisely take into account the returns for such expenses as shown by the crop yields (Table 3, page 4), by the returns for feed fed to livestock (Tables 7, 8, 9, and 10 on pages 15, 16, 17, and 19), and by the conditions in which the farm and farmstead are kept.

DEFINITIONS OF SOME WORDS AND EXPRESSIONS USED IN THIS REPORT

Cash balance. Page 2. The cash balance is the difference between the cash farm income and the cash farm expense. It is what the farm business furnishes during the calendar year for family living, savings, life insurance, and payments of old accounts, interest, and principle of debts.

Returns for capital and management. Page 3. The returns for capital and management are the difference between the total farm expense and the total receipts and net increases on the accrual, or inventory, basis. The total farm expense includes the total expenses and net decreases, including the family and operator's labor and depreciation on improvements and machinery.

Rate earned on investment. Page 3. The rate earned on investment is the return for capital and management for each \$100 invested in land, operating capital, and improvements (not including the residence).

Crop yield index. Page 4. The crop yield index for any farm, as used in this report, is the percentage that the yield of all grain crops on the farm is of the average yield on all farms.

Crop system rating. See page 13.

Days of productive work. See page 12.

Cattle efficiency index. Pages 4, 14, 16, and 17. The cattle efficiency index for any farm is the percentage that the return from cattle on the farm is of what the return would have been if the cattle had been fed with the average return per \$100 feed for that class of cattle.

Sheep, hog, and poultry efficiency indexes. Pages 4, 14, 15, and 19. These numbers are calculated the same as are those for cattle.

All livestock efficiency index. Pages 4 and 14. The livestock efficiency index for any farm is the percentage that the return from all livestock is of what the return would have been if each class of livestock had been fed with the average return for \$100 feed.

Price index. Pages 4 and 20. The price index for any farm is the percentage that the total value of the sales of grain, livestock, and livestock products on that farm is of the total value if each product had been sold at the average price of that product on all farms.

Labor accomplishment index. Pages 4 and 21. The labor accomplishment index for any farm is the percentage that the average labor cost on farms having the same amount of work on crops and livestock as that farm is of the labor cost on that farm. It is really a measure of the number of acres worked and the amount of livestock handled per man on farms having about the same amount of work on crops and livestock.

Horse and machinery accomplishment index. Pages 4 and 21. These numbers are calculated the same as are those for labor.

Feed charge (and returns) per 100 pounds of beef or 1000 pounds of milk. Experiment station data show that it requires approximately the same value of feed to produce 100 pounds of beef as to produce 1000 pounds of milk. Consequently, in order to show the relative cost of and returns for cattle products on farms in which the relative amounts of beef and milk vary greatly, this factor has been found useful.

a/ General farms have less than 40% of their income from any one source or have have 40% or more from each of two sources. General livestock farms have 60% or more of their income from productive livestock, and mixed income farms have less than 60% of income from productive livestock

Standards for calculating the crop system rating. A crop system rating was calculated for each farm by multiplying the acres of each crop on tillable land by the factors given in Table 5, and then by dividing the total rating for all crops by the total acres of tillable land. The ratings obtained on different farms are approximately in proportion to the average net earnings per acre to be expected on the tillable land if other factors than the crop system were equal. The crop ratings were made up from various experimental data. No credit was given to legumes for soil-improvement value.

Table 5.--Standards for Calculating a Crop System Rating and for Calculating Days of Productive Labor

Mogs per 100 pounds produced		.26
Sheep per animal unit		3.00
Hens per 100 head		29.00
*		

Standards for calculating days of productive labor. The standard days of man labor required for the production of crops and livestock, as shown in Table 5, are based on many years of complete cost studies conducted by the Department of Agricultural Economics. Estimates for uncommon crops were made by applying the same figure used for similar common crops. These standard requirements were applied to the acres of crops and amounts of livestock on each farm in order to calculate the total days of productive work for the farm.

a/ Other crops include clipped oats, soybeans plowed under, and clovers and timothy cut for seed, canning and truck crops, and other miscellaneous crops.

The crop system. The percent of tillable land occupied by high- or low-net-income crops is an important factor affecting net farm incomes. The crop system rating used in this report indicates the relative net income value of all crops grown on tillable land. Although the crop system rating of the 109 farms with highest earnings differed very little from that of the 109 farms with lowest earnings, individual farms showed marked differences. This fact is brought out in the Farm Efficiency Chart on page 5, where one-fifth of the higher-valued-land farms had crop system ratings of 69.5 to 79.4 while another one-fifth had ratings of only 54.5 to 62.6.

Of the 175 farms in the Farm Bureau Farm Management Service in Livingston, McLean, Tazewell, and Woodford counties during 1936, 1937, and 1938, the 35 farms with the highest crop system rating had more income, by \$438 per farm per year, than did the 35 farms with the lowest rating. Many farmers fail to realize on the high income value of certain legume crops because they neglect to utilize these crops fully, either as seed-producing crops or as feed for livestock.

Efficiency of Livestock Enterprises

On livestock farms, the efficiency with which the livestock is produced or purchased, fed, and marketed is as important in making the net farm income high or low as are all the other factors combined. (See Bulletin 444, "Farm Practices and Their Effects on Farm Earnings," page 554.)

Since about 60 to 80 percent of all costs of producing livestock is for the feed, the returns from livestock for \$100 feed fed is the most satisfactory single measure of efficiency for each class of livestock. The average returns per \$100 feed fed to different classes of livestock and the average prices received for stock sold were as follows:

		Number of herds	Returns per	Price received per 100 pounds sold
1.	Beef cow herds	41	\$ 146	\$ 9.03
2.	Dairy cow herds	166	204	7.32
3.	Dual purpose cow herds	30	162	7.57
4.	Beef cow herds and dairy cow herds	20	167	8.22
5.	Feeders bought	96	131	9,57

3.	Native flocks and feeder lambs bought	18	133	8.35
	200000	10	100	0.00
	Hogs	474	144	6.38
	Poultry	247	195	

When calculations were made for the value of feed fed, grain was charged to livestock at average farm prices for Illinois, reported by the Illinois Cooperative Crop Reporting Service as follows:

	Jan. to Aug.	Sept. to Dec.
Corn	\$.41	\$.46
Oats	•26	.31
Wheat	•62	.79
Barley	• 40	.44
Soybeans	.72	.79
Rye	• 38	• 48

Hay and silage were charged at inventory prices as determined on each farm. Pasture was charged at five cents per day per animal unit. An animal unit is considered as one mature horse or cow or the equivalent of young animals. (continued on page 18)

^{1/} Bulletin 444 is based on records kept by cooperators in the Farm Bureau Farm Management Service during the ten years 1925-1934.

(Continued from page 14)

Sheep. Only farms having three or more animal units in sheep and keeping complete records were used in the comparisons shown in Table 7, page 15. The average native flock paid well for the feed at the prices charged; especially since more than 75 percent of their feed consisted of hay and pasture which have little or no market value. Feeder sheep paid a good return of \$136 for each \$100 of feed fed.

Cattle. Only farms having five or more animal units in cattle and keeping complete records were used in the comparisons shown in Table 8, pages 16 and 17. The very wide spread in returns per \$100 feed between the cne-third best and one-third poorest herds is very apparent for each class of cattle.

Pairy herds returned an average of \$204 for each \$100 feed fed. Relatively low feed costs, good returns for dairy products, and high production per cow were important in causing the difference of \$272 per \$100 feed for the 55 most profitable herds and only \$147 per \$100 feed for the 55 least profitable herds (Table 8, page 16).

Feeder cattle gains appeared to be more dependent on low feed costs per 100 pounds gain than on the quality of cattle fed and the spread between buying and selling prices. The 32 most profitable herds, as compared with the 32 least profitable, had \$2.60 lower feed charges per 100 pounds, but only \$.29 more spread (Table 8, page 17).

Dual purpose and beef cow herds paid well for their feed in 1939, even when they were charged with hay at market value and pasture at \$.05 per day-\$1.50 per month. The 10 most profitable dual purpose herds returned a very nice profit as compared with that of the 10 least profitable herds, due partly to a higher production of both beef and milk per cow in the herd but due more to the very low feed costs of only \$4.20 per 100 pounds of beef or 1000 pounds of milk (Table 8, page 16).

Improving the quality of the breeding stock will increase the returns for feed fed to many dual purpose and beef cow herds.

Hogs. Only farms producing 10,000 pounds or more of pork were used in the comparisons shown in Table 9. Hogs proved very profitable in 1939 because of low feed requirements. One-third of the farms reported an average feed cost of only \$3.14 per 100 pounds of pork produced, but another one-third reported feed costs of \$4.40 per 100 pounds. This difference of \$1.26 per 100 pounds of pork produced was much more important than was the difference of \$.29 per 100 pounds in the average prices received.

Poultry. Flocks having 50 or more hens were used in the comparisons in Table 10. Low egg production per hen and high feed costs are evidently responsible for much of the low returns per \$100 feed fed on the farms having the poorest flocks.

a/ The average selling prices of beef and mutton from the classes of cattle and sheep produced on the farm were used in calculating the value of products sold (page 14).

Influence of price on farm earnings. Price of products sold is, of course, one of the important factors that affect farm earnings. However, it is not as important as other factors in causing the great differences in earnings on farms of the same type during any one year or period of years. In individual cases, a specially good or poor price for the major products sold may be a very influential factor in determining the net farm income. Usually, however, each cooperator will find that production costs are much more effective in making incomes high or low than are the prices of products sold. If his prices are consistently low from year to year, each cooperator may well study the reasons for such low prices.

Income from use of machinerya/a/ This figure includes the automobile	\$	\$ 130	\$ 159	\$ 75	\$ 118

a/ This figure includes the automobile.

Labor costs. Labor costs were slightly lower on the 109 farms with the higher valued land and with the highest earnings than on the average of farms with the same amount of work on crops and livestock. Despite lower labor costs, the most profitable farms produced better-than-average yields of crops and had better-than-average returns from feed fed to livestock (Table 3, page 4). On the other hand, labor costs were \$126 higher per farm on the 109 least profitable farms with the higher valued land even though they had low crop yields and low returns from feed fed to livestock.

Power amd machinery costs. Low power and machinery costs for the amount of work done increased the net farm earnings on many farms. The average cost of \$914 per farm on the 109 most profitable farms with the higher valued land was \$169 less than was the average cost on farms having about the same amount of work on crops and livestock.

Anyone who finds his power and machinery costs particularly high may locate the source of such high costs in his auto, truck, tractor, or other machinery accounts by comparing his record with that of the average of farms similar to his. In making such a comparison, the size of farm and the amount of tillable land need to be considered.

Influence of Price Changes on Illinois Farm Incomes

All feed and grain, livestock, and other farm property on accounting farms must be valued at both the beginning and the end of the year. Prices at inventory time, therefore, have a marked influence on farm earnings. The influence is greatest where large stocks or supplies are on hand at inventory time; for example, a much larger supply of farm products was found on Illinois farms December 31, 1939, than a year earlier. In fact, grain and livestock inventories have been increasing on Illinois farms since the drouth of 1936 as a result of three years of exceptionally high crop yields and the influence of Agricultural Adjustment Programs which have caused farmers to grow more hay and pasture and to store corn on farms under seal. According to estimates made by the Bureau of Agricultural Economics, U.S.D.A., 356 million bushels of corn were on Illinois farms January 1, 1940, as compared with 325 million bushels January 1, 1939.

Livestock numbers on Illinois farms increased sharply in 1939 even though 62 million bushels of 1937 and 1938 corn were placed under seal at the end of the year and 83 million bushels of 1939 corn were sealed by March 31, 1940. The following data indicate the percentage increase in livestock numbers on 2520 accounting farms in Illinois from the beginning to the end of 1939: dairy cows, 2 percent; beef cows, 21 percent; feeder cattle, 17 percent; feeder lambs, 24 percent; brood sows, 4 percent; spring pigs, 38 percent; summer pigs, 23 percent; and fall pigs, 28 percent. Hog numbers have been increasing since 1935 and have now attained record levels; for example, 13.5 sows farrowed per farm on accounting farms in 1939 as contrasted with 9.9 sows farrowed per farm in 1938. The increase in beef cattle numbers is a part of the general up-swing taking place over the entire United States, and it may be expected to continue for several years.

These data indicate that supplies of both feed and livestock were greater at the time the 1939 closing inventory was taken than at any other inventory period in several years, and price changes, therefore, are important in interpreting farm earnings for the state and for farming-type areas in 1939.

Prices of important farm products.--Frices for all crops as well as for beef cattle and sheep were higher at the end of 1939 than they were at the beginning, whereas prices for horses, hogs, and poultry were lower. Most of these price increases occurred during the last four months of the year.

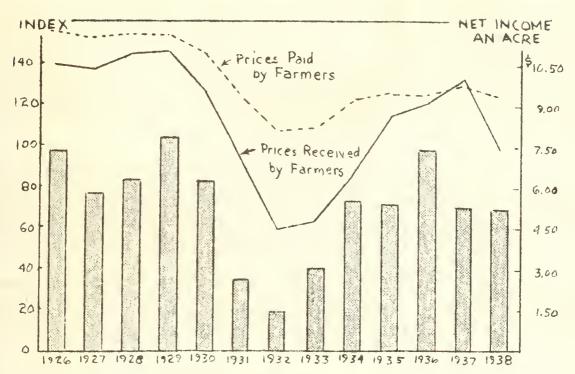

Fig. 1.--Average net cash income an acre (unpaid labor deducted) on Illinois accounting farms, prices paid by farmers in the United States, and prices received by Illinois farmers, 1926-1938.

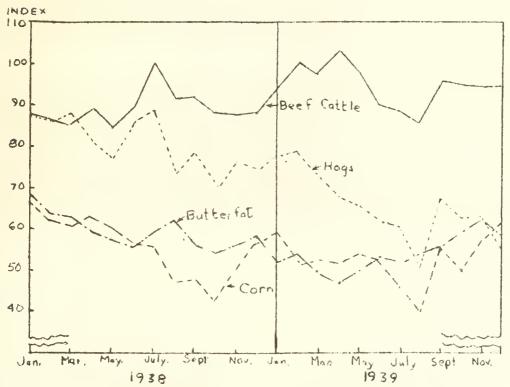

Fig. 2.--Monthly price indexes of the average farm prices of corn, kogs, beef cattle, and butterfat, 1938 and 1939.

(1924-1929 * 100)

Farm earnings are influenced by the average price received for farm products during the year as well as by the values at inventory time. Although nearly all commodities were higher in price at the end of the year than at the beginning, prices received for the following commodities averaged lower in 1939 than in 1938 by these amounts: corm, 2 cents per bushel; wheat and soybeans, 1 cent per bushel; hogs, \$1.50 per hundred; butterfat, 2 cents per pound; eggs, 3 cents per dozen; and chickens, 2 cents per pound. The prices for other commodities averaged higher in 1939 than in 1938 by the following amounts: oats, 4 cents per bushel; beef cattle, 50 cents per hundred; lambs, 42 cents per hundred; wool, 4 cents per pound; and apples, 12 cents per bushel.

Variation in earnings between the various type-of-farming areas is influenced by the relative prices of grains, livestock, and livestock products. In 1939 cs in 1938 livestock had a price advantage over grain, but the advantage was not as marked as it was in 1938. The prices for meat animals dropped from 116 to 110 percent of the 1910-14 average, grains from 74 to 72 percent, chickens and eggs from 106 to 94 percent, and dairy products from 106 to 104 percent.

The corn-hog ratic also narrowed during the year to the disadvantage of the hog enterprise. The amount of corn equal in value to 100 pounds of hogs dropped from 19 bushels in February to 11 bushels in December (based on farm prices). Unfavorable feeding ratios will discourage expansion in hog numbers in 1940.

Crop Yields in Illinois, 1939

Crop yields in Illinois in 1939, as in 1938 and 1937, were unusually high. The weighted average yield of corn, oats, wheat, and soybeans was 133 percent of the 10-year average, 1929-1938. Corn contributed more than did any other crop to the high average yields. The yields of the various crops expressed in percentages of the 1929-1938 averages were: corn, 150; soybeans, 129; wheat, 121; and pata, 97.

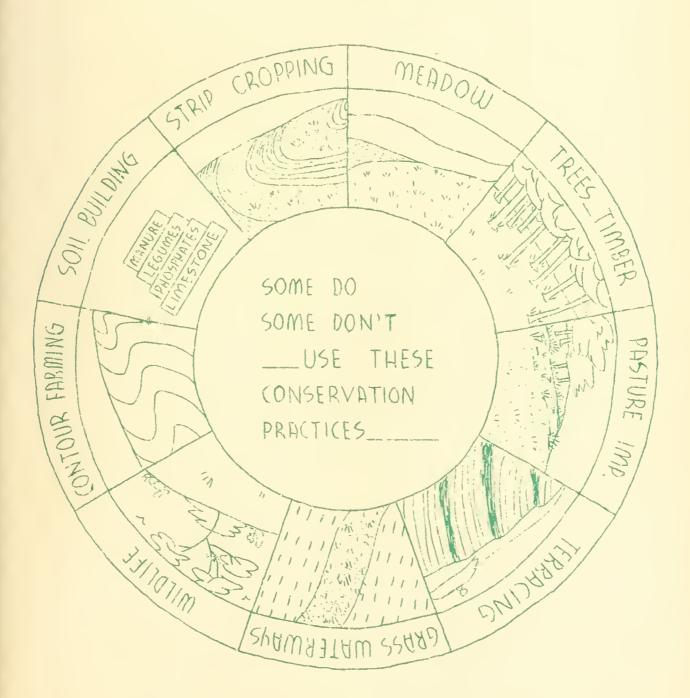

Crop yields in all counties except Massac were above the 10-year average (1929-1938 = 100), but wide variations in yields occurred between individual counties and groups of counties. Four counties along the Ohio River had crop yield indexes under 105. In contrast to these counties, 31 were over 136. Many of the counties with the highest yields were in two groups, those located in southwestern and east north central Illinois. Crop yield indexes were adversely affected in southeastern Illinois by the wheat crop and in northern Illinois by low oat yields. Fifty-five counties, which were well-distributed over the state, had crop yield indexes from 121 to 135.

Fig. 3.--Crop yields for 1939, compared with 10-year average yields (1929-1938) for the same county. The indexes are based on county yields of corn, cats, wheat, and soybeans. (Data from Illinois Cooperative Crop Reporting Service.)

SUMMARY

In drawing conclusions from the information in this report on the Edwardsville Soil Conservation Area, the reader should remember that these data represent results for only one year and that the farm plans of the conservation cooperators have not been in operation for sufficient time to reflect much change in crop yields or to permit the completion of necessary adjustments in the livestock enterprises. However, the data do exhibit certain trends and facts which serve as indicators and which might be stated as general conclusions.

- 1. Although the conservation cooperating farms were still in a transition stage, their average incomes were comparable to those on the noncooperating farms. With the better land use and greater emphasis on soil conservation and soil improvement found on the cooperating farms, incomes on these farms should increase in relation to those on the noncooperating farms as time passes and as the farm business becomes adjusted to the increased production of erosion-control and soil-improvement crops. In the meantime, these conservation cooperating farms are maintaining their soil resources as a heritage for future generations.
- 2. The conservation program entails additional expenses for items such as limestone, phosphate, fertilizer, legume seeds, fencing, terraces, and other necessary means of erosion control and soil improvement. Nevertheless, the total farm expenses in this area average no higher on the conservation cooperating farms than on the noncooperating farms, in large part due to the fact that the conservation cooperating farmers have made an effort to do much of the work in connection with the conservation program during their spare time and without additional outlays and to the fact that they apparently have curtailed expenditures for other items in order to achieve the goal of soil conservation and soil improvement on their farms.
- 3. On the bases of soil rating, size of farm, and proportion of land tillable, the conservation cooperators have made considerable advancement in the

adjustment of their land use to their soil resources, especially in comparison with the noncooperating farms.

- 4. A wide variation exists in size of farm and quality of soil resources available on these farms, and in order to have an income sufficient for a good standard of living, the operators of the small, rough land farms must do an especially good job of adjusting their land use to their soil resources and, furthermore, must utilize efficiently the crops grown on the farm.
- 5. Evidently the operators on farms of medium soil ratings have not recognized their soil-conservation and soil-erosion problems to the extent that farmers on the farms with low soil ratings have, and the former have not adjusted their land use and system of farming accordingly because the net earnings in 1939 were consistently lower on the farms with medium soil ratings than on the farms with low soil ratings.
- 6. Tenure problems in this area center primarily on the rented-land farms, on the part-owner-operated farms, and on the unrelated-tenant-operated farms. Field renting is common on the part-owner-operated farms; and the field or fields operated in addition to the farm on which the operator resides are cropped unsparingly, are rapidly depleted of their natural resources, and are subject to serious erosion problems. Many of the tenant farmers who are not related to the owner of the farm do not have sufficient equipment to meet the legal regulations to permit them to produce milk for the fluid milk market. As a result their farms tend to be operated as grain farms, and insufficient erosion-resisting crops are grown to control erosion and to maintain or improve soil fertility.
- 7. In the analysis of the total livestock enterprise, large quantities of good-quality legume and nonlegume roughage were utilized efficiently by livestock on many farms, and earnings on these farms were maintained at a high level.

- 8. Dairy cattle made more efficient use of roughages in this area than did beef cattle. Dairy cattle are more adaptable, and the dairy enterprise itself results in higher net farm incomes than the beef cattle enterprise. This area is adjacent to a whole milk market; farms are small and soils require the production of large quantities of roughage in order to control erosion and conserve the land.
- 9. The dairy cost analysis indicates that, by careful selection and culling of the herd, high milk production per cow can be secured on a high roughage ration and that milk can be produced at a relatively low cost, especially from the standpoint of "out-of-pocket" costs. Based on the herds studied, milk was produced more efficiently and at lower costs by the high roughage-consuming herds.
- 10. More consideration might be given to the use of native flocks of sheep in order to utilize some of the roughages produced as a result of the adoption of the conservation program, particularly on the rougher lands.
- 11. The products of the well-planned conservation program, that is, good-quality legume hays and legume and nonlegume pastures, can be utilized profitably through well-managed livestock enterprises with the result that soil resources will be protected and desirable farm incomes will follow.

SUMMARY OF FARM ACCOUNT RECORD STUDY ON 90 FARMS
IN EDWARDSVILLE SOIL CONSERVATION AREA,
MADISON AND ST. CLAIR COUNTIES, ILLINOIS, 19391/

By E. L. Sauer, C. H. Krusa, F. J. Reiss, and H. C. M. Case²/

This report for the year 1939 is the first of a planned series of annual reports based on complete farm account records of farmer cooperators in the Edwardsville Soil Conservation Area. These farm account records are from farmers who have signed agreements with the Soil Conservation Service to operate their farms in accordance with a planned program of soil conservation and erosion control and from farmers who are operating farms not under agreement with the Soil Conservation Service.

Madison and St. Clair counties are located in Illinois Type-of-Farming
Area 6, which is classified as the wheat, dairy, and poultry section in Illinois
Bulletin 403, "Types of Farming in Illinois." Wheat is the major crop, and dairying is the major livestock enterprise. The land in these two counties ranges from
level land with no erosion problems to rough rolling land with serious erosion
problems. Timber, prairie, and bottomland soils are found on the farms included
in this study, but timber soils are predominant.

^{1/} The Department of Agricultural Economics, University of Illinois College of Agriculture, the Madison and St. Clair County Farm Bureaus, the Soil Conservation Service, and the Bureau of Agricultural Economics, United States Department of Agriculture cooperated in this study.

^{2/} T. W. May, farm adviser in Madison county, and B. W. Tillman, farm adviser in St. Clair County, cooperated in the organization and supervision of the farm account record study.

^{3/} These farm account records were kept in the Illinois Farm Account Book under the supervision of C. H. Krusa of the Operations Division of the Soil Conservation Service. The accounts contained a record of the inventory taken at the beginning and end of the year on land, buildings, livestock, machinery, equipment, feed, and grains and a record secured from the farm during the year on receipts, expenditures, land use, crop production, livestock production, feeds used for each class of livestock, and contributions to family living.

The farm account record analysis which follows is primarily statistical, and the data are summarized in tabular form. Detailed conservation survey maps were made of each farm included in the study, and a soil rating was computed for each farm. This soil rating is a composite measure of soil type, percent of slope, and degree of erosion as related to productivity. Its use makes possible a comparison of farms having comparable physical soil resources. Detailed dairy cost account records were secured on 54 of the farms included in this study, and an analysis of these records is included in this report.

Comparison of Soil Conservation Cooperating and Noncooperating Farms

A comparison of 51 conservation cooperating farms with 35 noncooperating farms is made in Tables 1 and 2, pages 17 and 18. Some of the 35 farms not cooperating with the Soil Conservation Service have been following for many years a sound system of farming, including good land use and the use of soil conservation practices, and still others of these 35 farms are located on level land, and, generally speaking, do not have a serious soil-erosion problem. On the other hand, most of the 51 conservation cooperating farms are in a transition stage, and full benefits of the adoption of the conservation plan will not be evident for several years. 1

Generally speaking, investments, receipts, expenses, and earnings were similar on the 51 conservation cooperating farms and the 35 noncooperating farms (Table 1, page 17). The investment in land and buildings was higher on the 51 cooperating farms, but the livestock investment was lower on these farms. The two groups of farms were comparable in size, the 51 cooperating farms averaging 163 acres and the 35 noncooperating farms averaging 161 acres. Soil ratings were about the same for the two groups of farms, the 35 noncooperating farms having a slight advantage (Table 2, page 18). (The soils are rated from 1, the best, to 10, the poorest.)

^{1/} The Soil Conservation plan was initiated on 4 farms in 1935, 11 farms in 1936, 15 farms in 1937, 15 farms in 1938, and 6 farms in 1939.

Land Use: The 51 conservation cooperating farms had a slightly smaller percentage of their land area tillable, a smaller percentage of the tillable land in oats and nonlegume hay and pasture, and a larger percentage of the tillable land in corn, wheat, soybeans, other crops, and legume hay and pasture than did the 35 noncooperators. The 51 conservation cooperators had 33.0 percent of their tillable land in soil-building legumes as compared with 25.8 percent on the farms of the 35 noncooperators (Table 2, page 18). This percentage indicates that the 51 cooperators not only are conserving their present soil resources but also are attempting to build up the fertility level of their farms.

Crop Yields: Due to extremely favorable growing conditions in 1959, crop yields averaged approximately 45 percent above normal for all farms in this area. However, the yields of different crops were influenced in varying degrees, and a possible distortion of the relationship of the crop yield index to soil productivity may have resulted. Nevertheless, crop yields were about the same on the two groups of farms, with the 51 cooperators having a slight advantage (Table 2, page 18). The conservation program has not been under way long enough, however, for the improved land treatment and land use to have a significant effect on crop yields.

Livestock: The 35 noncooperating farms fed more feed to livestock but had lower returns per \$100 feed fed to productive livestock than did the 51 cooperators (Table 2, page 18). Because the farm plans of the conservation cooperators are in a transition stage, these cooperators have not adjusted their livestock enterprise to their changed land use and have not increased their forage-consuming livestock sufficiently to utilize all of the added roughage that will be produced as a result of the adoption of the Soil Conservation plan.

Expenses: Horse and machinery costs and man-labor costs a crop acre were lower on the 51 cooperating farms than on the 35 noncooperating farms

(Table 2, page 18). During 1939 the 51 cooperators spent \$100 per farm for limestone, phosphate, fertilizer, and soil-building legume seeds, as compared with
only \$50 per farm spent for these items on the farms of the 35 noncooperators.

Total farm expenses were \$10.40 an acre on the cooperators' farms and \$11.03 an
acre on the noncooperators' farms.

Earnings: Net farm incomes were \$1,608 per farm, or \$9.87 an acre, on the 51 cooperating farms, as compared with \$1,587 per farm, or \$9.84 an acre, on the 35 noncooperating farms.

Inventory Changes, Cash Income, and Cash Expenses

A summary of the inventory changes, cash income, and cash expenses and a summary for all the account-keeping farms in this area for the past four years is presented in Table 3, page 19. Net earnings per farm and per acre were higher in 1939 than in any of the three previous years.

Soil Rating Related to Investments, Receipts, Expenses, Earnings, Land Use, Crop Yields, and Other Factors

After being divided between conservation cooperators and noncooperators, the 86 farms were classified into three groups, according to soil ratings, as follows: the best soils, or those having a rating under 4.75; the average soils, or those having a rating from 4.75 to 6.25; and the poorest soils, or those having a rating over 6.25. An analysis of the resulting six groups of farms is presented in Tables 4 and 5, pages 20 and 21.

The farms of the conservation cooperators in each soil-rating group are smaller in size and have larger investments an acre in land and in the total farm business than do the corresponding noncooperators. Furthermore, within each group the farms with the higher soil ratings are smaller in size and are inventoried at a higher valuation an acre than are the farms with the lower soil ratings. Total farm receipts and net inventory increases are highest on the cooperating farms

with high soil ratings and are lowest on the cooperating farms with low soil ratings (Table 4, page 20). Of the total farm income for the two groups, the proportion secured from productive livestock is higher for the noncooperators with the medium and the low soil ratings and is lower for the noncooperators with the high soil ratings. This proportion further indicates that the conservation cooperators, for the most part, have not as yet increased their livestock to correspond with the increased roughage produced as a result of the conservation program.

Expenses for limestone, phosphate, fertilizer, and soil-building legume seeds were higher on the farms of the conservation cooperators, and this fact indicates that they are building up their farms for future production. For both groups net earnings an acre were highest on the farms with the high soil ratings and lowest on the farms with the medium soil ratings (Table 4, page 20).

Land use followed a rather uniform pattern—the farms on the best soils tended to have a larger proportion of their farms in grain crops and a smaller proportion in legumes, particularly soil—building legumes, and the conservation cooperators tended to have a larger proportion of their farms in soil—building legumes than did the noncooperators. The smaller proportion of tillable land was found on farms with the medium soil ratings rather than on farms with the low soil ratings, but this situation is accounted for by the fact that a considerable proportion of the land on the farms of low productivity consists of level, impervious soils of rather low productivity.

For the most part crop yields were higher on the farms of the conservation cooperators than on those of the noncooperators. The crop yield index tended to follow the same trend as did the soil rating, and therefore a closer relationship between soil rating and crop yield index was found on conservation cooperators' farms than on the noncooperators' farms (Table 5, page 21).

Livestock efficiency was somewhat higher on each of the three groups of cooperators' farms than on the corresponding noncooperators' farms (Table 5, page 21).

Size of Farm and Soil Rating Related to Land Use and Other Factors

In an attempt to compare farms of similar size as well as similar soil ratings, the six groups treated in the previous section were further subdivided into those farms which were smaller than average in size and those farms which were larger than average in size. The data from the resulting twelve groups of farms are presented in Table 6, page 22 and 23. The size of the sample in the various groups is rather small, and since the data represent only one year, no attempt will be made to draw conclusions from the material in this table. However, this analysis does show the wide variation and lack of uniformity which exist even between farms in a given area, and it also shows certain general tendencies and certain principles of farm management, such as the importance of high crop yields, efficient livestock, and low operating expense, which are applicable regardless of size or type of farm. Furthermore, this analysis will enable the individual farmer to compare his farm with farms of similar size and similar soil ratings.

On the basis of the proportion of the tillable land in the various crops, the conservation cooperators in both size groups have more nearly adjusted their land use to their soil resources than have the noncooperators (Table 6, pages 22 and 23). The noncooperating farms in both size groups, and particularly those with low soil ratings, apparently did not have an adequate acreage of soil-building legumes to maintain or to improve their present soil resources. Although crop yields varied considerably, yields tended to correspond with soil ratings, and the smaller farms tended to have higher yields than did the larger farms.

Livestock accounted for a higher proportion of the farm income on the farms with the lower soil ratings than on the farms with the higher soil ratings.

Operating expenses per acre and per crop acre were higher on the smaller farms than on the larger farms, and they also tended to be higher on the noncooperators' farms than on the cooperators' farms. Although earnings varied considerably, they tended to be higher on the larger farms, but some of the smaller farms had fairly high incomes, particularly on the "per-acre" basis. The farms with the medium soil ratings in each group tended, however, to have lower earnings than did the farms in the other soil-rating groups.

Tenure Related to Land Use, Yields, and Other Factors

The conservation cooperating and noncooperating farms were divided into owner-operated, part-owner-operated, and tenant-operated farms on the basis of tenure (Table 7, page 24).

Based on soil ratings and land values an acre, the tenant-operated farms were better farms than were the owner-operated or part-owner-operated farms. The tenant-operated farms were also smallest in size, but the part-owner-operated farms were largest in size. Because of the field-renting system in which a farmer will rent one or more fields in addition to the land he owns, the rented land on the part-owner-operated farms is usually cropped rather "hard," and the proportion of legumes on the total area operated on these farms is usually lower than it is for the owner- or tenant-operated farms. A high proportion of the tenant operators in this area are related to the owners; and, in part at least, this relationship accounts for the land use on these farms being comparable to the land use on the owner-operated farms. When the soil ratings are taken into consideration, crop yields are found to be much lower on the tenant-operated farms than on the owner-operated farms. However, the owner-operated farms fed more livestock than did the tenant-operated or part-owner-operated farms.

Expenses for soil conservation and soil improvement (limestone, phosphate, fertilizer, and legume seeds) were much higher on the conservation cooperating farms which were tenant-operated and part-owner-operated than on the corresponding noncooperating groups. On the other hand, net farm earnings were highest on the owner-operated farms and lowest on the part-owner-operated farms.

Livestock Related to Soil Conservation

Livestock occupies an important position in a Soil Conservation program since such a program frequently calls for the production of hay and pasture and since livestock offers the best means of utilizing these crops. Therefore, an economic study of soil conservation as it applies to the farm would not be complete without some consideration of the livestock enterprises which utilize the products of a conservation program. Detailed feed records were kept on the several livestock enterprises on the farms included in this study. An analysis of these livestock enterprises follows.

Use of Roughages Related to Livestock Returns

An analysis, including all classes of livestock, was made of the relation of the use of roughages to livestock returns. Roughages, as used in this report, include hay, straw, pasture, silage, fodder, and stover. The 90 farms were divided into two groups based on the value of roughages fed as compared with the total value of feed fed. On 45 farms roughages constituted 42 percent or more of the value of all feed fed to all livestock, and these farms are compared with 45 farms on which roughages accounted for less than 42 percent of the total value of all feed fed to all livestock. The two groups fed about the same total value of feed to all livestock, but the high-roughage group fed \$1,090 of feed to cattle and sheep as compared with \$813 of feed fed to the same roughage-consuming livestock in the low-roughage group (Table 8, page 25). Roughages constituted 52

percent of the total value of feed fed on the high-roughage group of farms and 32 percent on the low-roughage group. The quality of roughages was better on the high-roughage farms. Total livestock returns and returns per \$100 feed fed to all livestock were slightly higher on the high-roughage farms. The high-roughage farms had lower soil ratings, less tillable land, and fewer total acres than did the low-roughage farms, but the low-roughage farms had higher net farm incomes, both on a total farm and on a "per-acre" basis (Table 8, page 25). It is significant that these high-roughage feeding farms were able to market these roughages at a good price and that the livestock paid high returns after being charged for all feeds, including some otherwise urmarketable roughage. The utilization of the roughages resulted in higher farm incomes and also in soil improvement from the manure produced as a result of the livestock feeding operations.

Dairy Enterprise

On 73 of the 90 farms, dairying was a major livestock enterprise. For analyzing purposes the dairy farms were classified according to the proportion of their total feed value that was roughage. On 41 of the farms, 60 percent or more of the total feed costs (an average of 65 percent) was roughages, and on 32 of the farms, less than 60 percent of the total feed costs (an average of 51.8 percent) was roughages (Table 9, page 26). The high-roughage herds were somewhat larger, were fed slightly more feed, and had \$10 higher returns per \$100 of feed fed than did the low-roughage herds. Milk production was 459 pounds less per cow in the high-roughage herds, but the total cost of feed fed the entire dairy herd averaged 4 cents less per 100 pounds of milk produced on these farms than it was in the low-roughage herds. The high-roughage farms had slightly lower soil ratings, fewer acres, and a slightly higher net income an acre. Since they fed more high-quality roughages and less grain and protein supplement, they had less "out-of-pocket" costs in connection with their dairy enterprise than did the low-roughage farms.

Beef Enterprise

The beef enterprise was a major livestock enterprise on only 16 of the 90 farms included in this study. The type of beef enterprise was variable, ranging from feeder cattle to beef-breeding herds, and one or more milk cows were also kept on most of these farms. The larger beef enterprises were more successful than were the smaller ones (Table 10, page 27). Feeder cattle made up a larger proportion of the beef enterprise on the best herds than on the poorest herds, and roughages accounted for a smaller proportion of the total feed cost of the best beef herds than of the poorest beef herds. Returns per \$100 feed fed beef cattle were \$151 for the best herds and only \$92 for the poorest herds. Based on the small sample of beef herds and the one year's data, the beef enterprise on the farms in this area did not offer as good an opportunity to market roughages advantageously as did the dairy enterprise, from the standpoint of either returns per \$100 feed fed or net income per farm and per acre (compare Tables 9 and 10, pages 26 and 27).

Sheep Enterprise

Native flocks of sheep were found on 16 of the 90 farms. The size of the flocks was small, but on the average the sheep made good returns for the feed fed, particularly when approximately 85 percent of the value of their feed was from roughages which have little or no market value. There was a wide variation in the efficiency with which the sheep enterprise was conducted, the 8 best flocks having returns of \$198 for each \$100 feed fed as compared with returns of \$77 for each \$100 feed fed to the 8 poorest flocks (Table 11, page 28).

Hog Enterprise

An analysis of the hog enterprise on 81 of the farms raising hogs and on the 27 farms having the most profitable hog enterprises and the 27 farms having

the least profitable hog enterprises is shown in Table 12, page 29. The most profitable hog enterprises were larger than the least profitable ones were, and the former apparently fed a better balanced ration and secured more efficient gains. Feed costs for the most profitable hog enterprises were \$3.54 for each 100 pounds of pork produced as compared with \$5.54 per 100 pounds of pork produced for the least profitable hog enterprises (Table 12, page 29).

Poultry Enterprise

In the analysis of the poultry enterprise, only those flocks were included to which \$50 or more of feed were fed during the year. An analysis of the one-third most profitable flocks, the one-third least profitable flocks, and an average of all flocks is shown in Table 13, page 30. Returns from the poultry enterprise varied widely. High egg production per hen combined with efficient feeding and other factors of good poultry management paid dividends on the best flocks.

Cost of Producing Milk Related to Conservation

In connection with the general farm account records, detailed dairy cost of production records were kept on 54 of the 90 farms included in this study. After the elimination of those records which were not comparable because of size of herd and because of incomplete monthly feed records, 48 records were left, and they are included in the dairy cost analysis presented here. In order to study the relationship between the use of roughages, that is, the products of a conservation program, the cost of milk production, and other pertinent factors, the 48 records were divided into two equal groups based on the proportion that roughages were of the total value of feed fed the milk cows. Grains, hay, fodder, stover, and silage were valued at average farm prices, and pasture was valued at 6 cents per pasture day. There were 24 herds for which roughages accounted for over 69

percent of the total value of feed fed (an average of 74 percent) and 24 herds for which roughages accounted for less than 69 percent of the total value of feed fed (an average of 60 percent). All these herds are a select group, a majority of them being in the Dairy Herd Improvement Association, and they represent herds which are better than average. The higher roughage-consuming herds produced an average of 7,960 pounds of 3.5 milk per cow or only 88 pounds less than the 8,048 pounds of 3.5 milk per cow produced by the lower roughage-consuming herds.

The feed cost of producing 100 pounds of milk in 1939 was 65 cents on the higher roughage-consuming herds and 77 cents on the lower roughage-consuming herds. This feed cost was lower every month during 1939 on the higher roughage-consuming herds than on the lower roughage-consuming herds (Table 14, page 31). Likewise, the total cost of producing 100 pounds of milk was lower on the higher roughage-consuming herds. Therefore, feed cost and total net cost per cow were lower and net profits per cow were higher on the higher roughage-consuming herds (Table 14, page 31). The higher roughage-consuming herds were fed less grain and protein concentrates and more hay, silage, and pasture per cow than were the lower roughage-consuming herds. Corn silage was fed to 15 of the higher roughage-consuming herds and 18 of the lower roughage-consuming herds. However, much of the roughages fed the higher roughage-consuming herds consisted of high-quality legume hay and pasture as well as some legume silage. The millfeeds fed the higher roughage-consuming herds had a higher average protein content than did the millfeeds fed the lower roughage-consuming herds.

The monthly production of milk for the two groups of farms is shown in Table 15, page 32, and the quantities of feeds fed per cow per month for the two groups of farms are shown in Table 16, page 33. The proportion of the cows in milk in the herds each month was approximately the same for both groups of farms. Although a study of Tables 14, 15, and 16 shows that milk production per cow was

high and that feed cost per 100 pounds produced was low during the spring and early summer months when the cows were on good pastures, the records also show that these dairymen with the higher roughage-consuming herds found it profitable to feed some concentrates throughout the year. Although the above records cover a rather select sample and represent only one year's data, they do indicate that milk can be produced at a low cost with well-culled, high-producing herds by feeding a high proportion of good-quality legume roughages. Hence it appears that roughages, the products of a conservation program, can be utilized profitably by the dairy herd without resorting to large "out-of-pocket" costs for concentrates.

SUMMARY

In drawing conclusions from the information in this report on the LeRoy Soil Conservation Area, the reader should remember that these data represent results for only one year and that the farm plans of the conservation cooperators, for the most part, have not been in operation for sufficient time to reflect the improvement expected in crop yields or to permit the completion of necessary adjustments in the livestock enterprises. However, the data exhibit certain trends and facts which serve as indicators and which can be stated as general conclusions.

- l. Although the conservation cooperators were still in a transition stage, their average incomes were higher than were those on the noncooperating farms. With the better land use and greater emphasis on soil conservation and soil improvement found on the cooperating farms, the present incomes on these farms should increase in relation to those on the noncooperating farms as time passes and as the farm business becomes adjusted to the increased production of erosion-control and soil-improvement crops. In the meantime, these conservation cooperating farms are maintaining their soil resources as a heritage for future generations.
- 2. Crop yields on farms with comparable soil ratings were consistently higher on the farms of conservation cooperators than on those of noncooperators.

 These higher yields indicated that the sound land-use program on these farms, which includes approximately twice as large a proportion of soil-building legumes, is paying dividends and will continue to pay them.
- 3. Operating expenses, such as man labor and horse and machinery costs per crop acre, were somewhat higher on the cooperating farms than on the non-cooperating farms because the cooperating farms had fewer crop acres. However, the total farm expenses per acre in this area averaged no higher on the conservation cooperating farms than on the noncooperating farms, in large part due to the

fact that the conservation cooperating farmers have made an effort to do much of the work in connection with the conservation program during their spare time and without additional expenditure.

- 4. On the bases of soil rating, size of farm, and proportion of land tillable, the conservation cooperators have made considerable advancement in the adjustment of their land use to their soil resources, especially in comparison with the noncooperating farms. The land-use pattern on the noncooperating farms is such that soil resources on these farms are rapidly being depleted, and such that progressively lower yields and farm incomes are likely to follow.
- 5. In this cash-grain type-of-farming area, the size of farm was smallest on the poorer lands, and this fact indicates the need for land-use adjustments in these poorer areas. Farmers tended to crop these poorer lands rather hard in order to obtain a living from them. A wide variation exists in size of farm and quality of soil resources available on the farms in this area, and in order to have an income sufficient for a good standard of living, the operators of the small, rough land farms must do an especially good job of adjusting their land use to their soil resources and, furthermore, must utilize efficiently the crops grown on the farm.
- farms and on the part-owner-operated farms. The proportion of tenancy in this area is very high, and the major proportion of the tenants are not related to the owners of the farms. Part-owner operators tend to crop the land which they rent unsparingly. Similarly, the tenant operators tend to crop their farms unsparingly because, for the most part, these tenants have short-term leases (usually only one year) and because they know that if they have to move, they will not be compensated for any improvements or soil-conservation or erosion-control measures which they might adopt. The "toll" which is being exacted on these tenant-operated and

part-owner-operated farms is evidenced by the crop yields on these farms which average lower than those on owner-operated farms with similar soil ratings. In addition to tenant farmers and part-owner-operators cropping their land "harder," they are feeding less livestock and consequently have less manure to return to the soil.

- 7. The conservation cooperators have more livestock than do noncooperators, and a larger proportion of their livestock is of the roughage-consuming type. A considerable expansion of the livestock enterprises has accompanied the adoption of the conservation program in this cash-grain type-of-farming area.
- 8. In the analysis of the total livestock enterprise, large quantities of good-quality legume and nonlegume roughage were utilized efficiently by livestock on some farms, and earnings on these farms were maintained at a high level. Strictly speaking, the problem of soil conservation is one of land use, and most good land-use programs in this area call for more grasses and legumes and other forage and hay crops. Since the farm is an economic unit, in many instances a market must be found for the products of these soil-conservation and soil-improvement crops. Efficient roughage-consuming livestock offer one of the best markets for these products of the conservation program, particularly if good livestock management is practiced because milk, meat, and wool can be produced at a relatively low cost, especially from the standpoint of "out-of-pocket" costs.
- 9. More consideration might well be given to increased efficiency of the livestock enterprises on some of the farms in this area, and more attention should be given to the roughage-consuming types of livestock. In this area where most farms sell considerable quantities of grain, feed purchases may well be limited largely to high protein supplements.
- 10. The products of the well-planned conservation program, that is, good-quality legume hays and legume and nonlegume pastures, can be utilized

profitably through well-managed livestock enterprises with the result that soil resources will be protected and desirable farm incomes will follow.

ll. Contour farming on undulating and rolling land is a sound conservation practice which can be performed in this area at no apparent increase in the total farm operating expense and which results not only in the maintenance of soil and water resources but also in higher crop yields.

SUMMARY OF FARM ACCOUNT RECORD STUDY ON 110 FARMS IN LEROY SOIL CONSERVATION AREA, MCLEAN COUNTY, ILLINOIS, 19391/

By E. L. Sauer, C. C. Morgan, F. J. Reiss, and H. C. M. Case

This report for the year 1939 is the fifth in a series of annual reports based on farm account records of farmer cooperators in the LeRoy Soil Conservation Area; however, it is the first in a planned series of annual reports based on complete farm account records. 2/ These farm account records are (1) from farmers who have signed agreements with the Soil Conservation Service to operate their farms in accordance with a planned program of soil conservation and erosion control and (2) from farmers who are operating farms not under agreement with the Soil Conservation Service.

McLean county is located in Illinois Type-of-Farming Area 4a, which is classified as the cash-grain section in Illinois Bulletin 403, "Types of Farming in Illinois." Corn, oats, and soybeans are the major crops, and grain sales constitute the major source of income. Approximately 75 percent of the area is either undulating or gently rolling prairie land, 14 percent is level land which lies along the drainage ways, and the remaining 11 percent is either rolling or gently rolling timberland, much of which has been cleared of the native timber. Erosion is evident on all of the slopes in this area and is particularly noticeable in the areas which were formerly timbered. Continuous cropping with soil-

^{1/} The Department of Agricultural Economics, University of Illinois
College of Agriculture, the Soil Conservation Service, and the Bureau of Agricultural Economics, United States Department of Agriculture, cooperated in this study.

2/ These farm account records were kept in the Illinois Farm Account
Book under the supervision of C. C. Morgan of the Operations Division of the Soil
Conservation Service. The accounts contained a record of the inventory taken at
the beginning and end of the year on land, buildings, livestock, machinery, equipment, feed, and grains and a record secured from the farm during the year on
receipts, expenditures, land use, crop production, livestock production, feeds
used for each class of livestock, and contributions to family living.

depleting and clean-tilled crops has so depleted organic matter and available soil fertility in most of the area, that erosion is progressing at an increasing rate.

The farm account record analysis which follows is primarily statistical, and the data are summarized in tabular form. Detailed conservation survey maps were made of each farm included in the study, and a soil rating was computed for each farm. This soil rating is a composite measure of soil type, percent of slope, and degree of erosion as related to productivity. Its use makes possible a comparison of farms having comparable physical soil resources.

Comparison of Soil Conservation Cooperating and Noncooperating Farms

A comparison of 71 conservation cooperating farms with 39 noncooperating farms is made in Tables 1 and 2, pages 19 and 20. Most of the 71 conservation cooperating farms are still in a transition stage, and full benefits of the adoption of the conservation plan will not be evident for several years. 1 Although a comparison between two groups of farms sorted on the basis of cooperation with the Soil Conservation Service may have its weaknesses and limitations, such a comparison serves to present a condensed picture of fundamental differences between the two groups.

Physical Factors: The conservation cooperating farms averaged 21 acres larger in size than did the noncooperating farms, and the cooperating farms had a total farm investment which was \$8.00 an acre higher. On the basis of the average soil ratings, the conservation cooperating farms were slightly poorer than were the noncooperating farms; the former had an average soil rating of 2.53 and the latter an average soil rating of 2.18 (Table 2, page 20). (The soils are rated from 1, the best, to 10, the poorest.)

^{1/} The Soil Conservation plan was initiated on 7 farms in 1934, 21 farms in 1935, 18 farms in 1936, 10 farms in 1937, 11 farms in 1938, and 4 farms in 1939.

Land Use: The conservation cooperators had 90.4 percent of their land area tillable and had 77.6 percent of this tillable land in crops; the noncooperating farms had 92.6 percent of the land area tillable and had 82.5 percent of this tillable land in crops. The conservation cooperators devoted 28.7 percent of their tillable land to hay and pasture as compared with 22.9 percent devoted to hay and pasture on the noncooperating farms. These percentages indicate more intensive land use on the noncooperating farms. The conservation cooperating farms devoted one-fifth of all of their tillable land to soil-building legumes, and the noncooperating farms used less than half as many acres for the same purpose (Table 2, page 20). This land use suggests that the 71 cooperators are attempting to conserve their present soil resources and are also trying to build up the fertility level of their farms.

Crop Yields: Due to extremely favorable growing conditions in 1939, crop yields averaged approximately 35 percent above normal for all farms in this area. The conservation cooperating farms had significantly higher average yields of the principal grain crops than did the noncooperating farms (Table 2, page 20). The higher crop yields on the cooperators' farms were achieved in spite of the fact that the noncooperators had the higher soil ratings. These higher yields are an indication of good farm management, conservation practices, and the use of soil-building legumes and are not due to any inherent differences in soil productivity.

Livestock: Investments in cattle and hogs averaged over twice as large on cooperating farms as on noncooperating farms (Table 1, page 19). The cooperating farms fed \$1,572 of feed to productive livestock and had returns of \$144 per \$100 of feed fed; in contrast, the noncooperating farms fed \$822 of feed and had returns of \$163. The lower average returns per \$100 of feed fed on the

cooperating farms is largely due to differences in the kind of livestock to which the feed was fed and is not necessarily an indication of lower livestock efficiency. 1/

Expenses: Horse and machinery costs and man-labor costs per crop acre were higher on the cooperating farms than on the noncooperating farms. Total farm expenses an acre were comparable, however-those on the cooperators' farms were \$10.44 and those on the noncooperators' farms were \$10.33 (Table 2, page 20).

Earnings: Net farm incomes were \$2,510 per farm, or \$11.10 an acre, on the 71 cooperating farms, as compared with \$1,756 per farm, or \$8.56 an acre, on the 39 noncooperating farms (Tables 1 and 2, pages 19 and 20). These figures show that the conservation cooperators received dividends from their land-use program and had higher crop yields and larger livestock numbers.

Inventory Changes, Cash Income, and Cash Expenses

The average inventory changes, cash income, cash expenses, and a summary of earnings for all of the account-keeping farms in this area for the past four years is presented in Table 3, page 21. Cash receipts and net farm earnings were higher in 1939 than in 1938 or 1937, and inventory increases and cash farm expenses were higher in 1939 than in any of the three previous years. The large inventory increase in the feed and grain account was the result of higher crop yields and above-average prices for soybeans at the end of the year plus large amounts of sealed corn on the farms.

Soil Rating Related to Investments, Receipts, Expenses, Earnings, Land Use, Crop Yields, and Other Factors

After being divided between conservation cooperators and noncooperators, the 110 farms were classified into three groups according to soil ratings. The

 $[\]frac{1}{A}$ detailed analysis of the several livestock enterprises is given in Tables 9, 10, 11, 12, 13, and 14.

three groups are as`follows: the best soils, or those having a rating under 2.00; the average soils, or those having a rating from 2.00 to 3.00; and the poorest soils, or those having a rating over 3.00. An analysis of the resulting six groups of farms is presented in Tables 4 and 5, pages 22 and 23.

The normal influence of soil productivity is apparent within the two groups of farms (cooperators and noncooperators). Higher land values and larger total farm investments an acre are associated with the higher soil ratings. The conservation cooperators have both higher land values an acre and higher total farm investments an acre for each soil-rating class than do the noncooperators. Evidently the conservation cooperating farmers have done a better job of maintaining those factors which enhance the value of their farms.

In each soil-rating class the conservation cooperators had larger receipts from productive livestock and larger total farm receipts than did the non-cooperators. The poorer farms, both cooperators and noncooperators, had a larger proportion of their total farm receipts from livestock and a smaller proportion from grains than did the better farms. In each soil group cooperators received a larger proportion of their income from livestock than did noncooperators (Table 4, page 22).

Expenses for limestone, phosphate, fertilizer, and legume seeds were higher on the noncooperators' farms with medium and low soil ratings than on the corresponding cooperators' farms. This situation is accounted for by the fact that limestone and phosphate have been applied in previous years on the cooperators' farms and that, since a majority of the farms participated in the AAA program in 1939, many of the noncooperators found it necessary to apply limestone and phosphate to grow legumes in order to qualify for AAA payments. Although costs per crop acre for horses and machinery and for man labor tended to be higher on the cooperators' farms, the total farm expenses an acre were comparable on corresponding cooperators' and noncooperators' farms.

Within each soil-rating class gross receipts an acre and net receipts an acre followed a general trend in favor of the better soils and in favor of the cooperating farms. The advantage in favor of the cooperating farms ranged from a net of \$2.32 an acre on the poorest soils to a net of \$4.83 an acre on the best soils.

On both the cooperators' and the noncooperators' farms, the farms with the highest soil rating were largest in size, and those with the poorest soil rating were smallest in size.

Land use for all farms was definitely related to soil productivity as expressed by soil ratings. The better farms had a larger proportion of their tillable land in cultivated crops than did the poorer farms. In each group the conservation cooperators tended to have a smaller proportion of their tillable land in soil-depleting crops and a larger proportion in soil-building legumes than did the noncooperators. The noncooperating farms with low soil ratings had only 5 percent of their tillable land in soil-building legumes (Table 5, page 23).

The crop yield index tended to follow the same trend as did the soil rating. All crop yields were consistently higher on the farms of the conservation cooperators than on those of the noncooperators (Table 5, page 23).

The conservation cooperators fed a much larger volume of feed to livestock but received lower returns per \$100 fed than did the noncooperators. The lower returns per \$100 feed fed to livestock on the cooperators' farms was, for the most part, due to the following factors: (1) the feeding of more roughage (which would have little or no market value except as livestock feed); (2) inexperience in handling the larger volume of livestock; and (3) the type of livestock feed.

Size of Farm and Soil Rating Related to Land Use and Other Factors

In order to compare farms of similar size as well as of similar soil ratings, the six groups treated in the previous section were further subdivided into those farms which were smaller than average in size and those farms which were larger than average in size. (The average size of the 110 farms was 218.6 acres.) The data from the resulting twelve groups of farms are presented in Table 6, pages 24 and 25.

The size of the sample in the various groups is rather small, and since the data represent only one year, the statistical limitations of this analysis can be easily recognized. However, this analysis does show the wide variation and lack of uniformity which exist even between farms in a given area, and it also shows certain general tendencies and certain principles of farm management, such as the importance of good land use, high crop yields, efficient livestock, and low operating expenses, which are applicable regardless of size or type of farm. Furthermore, this breakdown on the basis of size of farm reveals the consistency of the data because the same general relationships exist between cooperators and noncooperators within comparable groups (Table 6, pages 24 and 25).

On the basis of the proportion of the tillable land in the various crops, the conservation cooperators in both size groups have more nearly adjusted their land use to their soil rescurces than have the noncooperators (Table 6, pages 24 and 25). The noncooperating farms in both size groups did not have an adequate acreage of soil-building legumes to maintain or to improve their soil resources. Although crop yields varied considerably, they tended to correspond with soil ratings, and the conservation cooperators consistently had higher crop yields.

Under comparable conditions of general soil productivity and size of farm, the conservation cooperators have higher land values, better land use,

more soil-building legumes, higher crop yields, more livestock, and larger gross receipts than do the noncooperators, and as a result all of these factors add up to higher net farm incomes.

Tenure Related to Land Use, Yields, and Other Factors

The conservation cooperating and noncooperating farms were divided into owner-operated, part-owner-operated, and tenant-operated farms on the basis of tenure (Table 7, page 26).

The same differences noted before between the cooperating and noncooperating farms appear in the respective tenure classes. Regardless of cooperation with the Soil Conservation Service program, both part-owners and tenants
cropped their land harder than did the owner-operators. From owner-operators to
part-owners to tenant operators, a progressive increase is found in the proportion
of tillable land in cultivated crops and a decrease is found in the proportion in
hay and pasture. In each tenure class a sounder system of land use and higher
crop yields were found on the farms of conservation cooperators than on those of
noncooperators. As evidenced by the crop yield indexes, crop yields corresponded
to the systems of land use on the different groups of farms, and the "toll" of
the heavier cropping systems was evident on the noncooperators' farms and on the
part-owner-operated and tenant-operated farms.

Less livestock was fed on the part-owner-operated and tenant-operated farms than on the owner-operated farms; however, the two former types of farms received the higher returns per \$100 feed fed because they fed less beef cattle and because feed normally constitutes a higher proportion of the total cost of producing beef cattle than other classes of livestock. Cooperating farms in each tenure group fed more livestock than did the noncooperators.

Part-owners and tenants had higher net incomes than did owner operators;
however, within the respective tenure groups, the cooperating farms had the higher
returns. Since the owner operators followed a sounder system of land use and had
more livestock and higher farm expenses, they are apparently more nearly maintaining their farm resources than are the part-owners or tenants.

Livestock Related to Soil Conservation

Livestock occupies an important position in a Soil Conservation program since such a program frequently calls for the production of hay and pasture and since livestock offers the best means of utilizing these crops. Therefore, an economic study of soil conservation as it applies to the farm would not be complete without some consideration of the livestock enterprises which utilize the products of a conservation program. Detailed feed records were kept on the several livestock enterprises on the farms included in this study. An analysis of these livestock enterprises follows.

Use of Roughages Related to Livestock Returns

An analysis, including all classes of livestock, was made of the relation of the use of roughages to livestock returns. Roughages, as used in this report, include hay, straw, pasture, silage, fodder, and stover. The 97 farms that had detailed feed records were divided into two groups based on the value of roughages fed as compared with the total value of feed fed. On 49 farms roughages constituted 30 percent or more of the total value of all feed fed to all livestock, and these farms are compared with 48 farms on which roughages accounted for less than 30 percent of the total value of all feed fed to all livestock. The high-roughage group fed \$985 of feed to all livestock and had returns of \$155 for each \$100 of feed fed as compared with \$1,693 of feed fed to all livestock and \$143 of returns for each \$100 of feed fed in the low-roughage

group (Table 8, page 27). Roughages constituted 37 percent of the total value of feed fed on the high-roughage group of farms and 18 percent on the low-roughage group. The quality of roughages was better on the high-roughage farms. The high-roughage farms had lower soil ratings, less tillable land, and fewer total acres than did the low-roughage farms, but the low-roughage farms had slightly higher net farm incomes due to larger amounts of livestock, somewhat higher crop yields, and better soils. It is significant that these high-roughage feeding farms were able to market these roughages at a good price and that the livestock paid high returns after being charged for all feeds, including some otherwise unmarketable roughage. By utilizing these roughages, the farmer is able to convert the products and byproducts of a soil conservation cropping system into a higher farm income, and he is also able to improve the soil with the manure produced as a result of the livestock-feeding operations.

Dairy Enterprise

On 34 of the 110 farms, dairying was a major cattle enterprise. For purposes of analysis, these dairy herds were classified according to the proportion of their total feed value that was roughage. On 17 of the farms, 65 percent or more of the total feed costs (an average of 78 percent) was roughages, and on 17 other farms, less than 65 percent of the total feed costs (an average of 56 percent) was roughages (Table 9, page 28). The high-roughage herds had returns per \$100 of feed fed which were \$23 higher than those for the low-roughage herds. Milk production was 421 pounds less per cow in the high-roughage herds, but the total cost of feed fed the entire dairy herd averaged 36 cents less per 100 pounds of milk produced on these farms than it was in the low-roughage herds. The high-roughage farms had lower soil ratings, fewer tillable acres, and consequently slightly lower net farm incomes than did the low-roughage farms. Since the high-

roughage farms fed more high-quality roughages and less grain and protein supplement, they had less "out-of-pocket" costs in connection with their dairy enterprise than did the low-roughage farms.

Beef Enterprise

Beef was a major cattle enterprise on 31 of the farms included in this study. On 16 of these farms (the high-roughage group), roughages accounted for an average of 59 percent of the total feed cost as compared with 26 percent on 15 of the farms (the low-roughage group). The type of beef enterprise was variable, ranging from feeder cattle to beef-breeding herds, and one or more cows were milked on most of these farms. The low-roughage herds fed more steers and fattening cattle than did the high-roughage herds, and their beef enterprise was much larger in size, averaging 51.3 animal units as compared with 20.2 animal units for the high-roughage herds. Returns per \$100 feed fed beef cattle were \$147 for the high-roughage herds and \$120 for the low-roughage herds (Table 10, page 29). These data indicate that farmers have not yet taken full advantage of the use of cattle as a means of marketing roughages produced under a soil conservation program.

Dual-Purpose Cattle Enterprise

On 32 of the farms, the cattle enterprise was of a dual-purpose nature. On the basis of the proportion of the total feed value that was roughages the herds were divided into two groups of 16 each. The size of herds was small, and the milk production per cow milked was relatively low. On the average, 34 percent of the cattle returns was from dairy sales, 37 percent from cattle sales, and the balance from inventory increases. The high-roughage herds had higher milk production per cow and higher returns per \$100 feed fed than did the low-roughage herds (Table 11, page 30). The returns from these herds indicate that a few farmers have used this class of livestock to good advantage as a market for roughages.

However, this class of livestock might be used to greater advantage in utilizing roughages produced as a result of a conservation program than is shown by the data in Table 11, page 30.

Sheep Enterprise

Sheep were raised or fed on 20 of the 110 farms. The size of flocks was small, but on the average the sheep made good returns for the feed fed, particularly when approximately 70 percent of the value of their feed was from roughages which have little or no market value. The efficiency with which the sheep enterprise was conducted varied widely; the 10 best flocks had returns of \$252 for each \$100 feed fed as compared with returns of \$98 for each \$100 feed fed to the 10 poorest flocks (Table 12, page 51). The best flocks were primarily native flocks, but considerable numbers of feeder sheep were purchased on farms with the poorest paying flocks. Sheep are especially adapted to utilize low-value roughages and pasture; therefore, efficient feeding of these feeds is an important factor in conducting a successful sheep enterprise.

Hog Enterprise

Hogs utilize comparatively small amounts of roughages, but, when hogs are properly managed, they can be used to advantage to increase the returns from feed grains, particularly in this surplus grain-producing area. Factors that make for successful hog enterprises are: (1) efficient feeding; (2) proper sanitation; (3) large numbers of pigs saved per litter; and (4) adaptation of the feeding and farrowing program to meet the normal seasonal price movements for hogs. The use of rotation legume pastures for the breeding herd, the sows with pigs, and the growing pigs is a profitable practice. An analysis of the hog enterprise on 84 of the farms raising hogs and on the 28 farms having the most profitable hog enterprises and the 28 farms having the least profitable hog enterprises is shown in Table 13, page 32.

Poultry Enterprise

In the analysis of the poultry enterprise, only those flocks were included to which \$40 or more of feed were fed during the year. An analysis of the one-third most profitable flocks, the one-third least profitable flocks, and an average of all flocks is shown in Table 14, page 33. Returns from the poultry enterprise varied widely. The possibilities of the poultry enterprise and its contributions to family living and the farm income are underestimated by many farmers with the result that the poultry enterprise is often not conducted as efficiently as it might be. High egg production per hen combined with efficient feeding and other factors of good poultry management paid dividends on the best flocks.

Crop Yields, Contour Cultivation Compared With Usual Field System on Same Farms

On a limited number of farms crop yields for corn, oats, and soybeans were secured on both contoured fields and on fields under the usual field system. Although the sample of farms is small and although the data represent only one year, these data are presented in Table 15, page 34, with the thought that they do give some interesting and pertinent considerations as well as some indication of results that might be expected under contour cultivation.

The data for the 3 crops are presented by soil-rating groups and are presented for all farms (Table 15, page 34). Corn yields for all of the farms averaged 4 bushels an acre more when they were planted and worked on the contour than when they were planted in the usual field system. On 11 farms, oats which were grown on the contour yielded an average of 7 bushels more per acre than did the oats grown without regard to contour. Soybeans yielded higher on the contour on the better soils and as high on the medium soils; but, due to the weighting

caused by the acreage of soybeans in the different groups, the average soybean yields for the 8 farms were 2 bushels an acre less when they were seeded on the contour than when they were seeded in the usual field system.

The results of crop yields on the contour compared with the usual field system (Table 15, page 34) might well be viewed in light of the following considerations: (1) Contour cropping has not been practiced long enough to obtain maximum effects; (2) fields cropped on the contour do not contain the best soils on the farm; (3) no information is available on the previous treatment of the fields under contour cultivation or of the fields farmed in the usual fashion; (4) the better soils appear to respond more rapidly to contour cultivation than do the poorer soils; and (5) on a majority of the farms yields for all of the crops in all three of the soil-rating groups were higher under contour cultivation than under the usual field system.
